Exaggerated sense of personal uniqueness	Acknowledge the adolescent's unique characteristics. At opportune times, encourage a more balanced perspective by pointing out that you had similar feelings as a teenager.
Idealism and criticism	Respond patiently to the adolescent's grand expectations and critical remarks. Point out positive features of targets, helping the teenager see that all societies and people are blends of virtues and imperfections.
Difficulty making everyday decisions	Refrain from deciding for the adolescent. Model effective decision making, and offer diplomatic suggestions about the pros and cons of alternatives, the likelihood of various outcomes, and learning from poor choices.

acceptance, and social support (Bell & Bromnick, 2003). The idea that others care about their appearance and behavior also has emotional value, helping teenagers hold onto important relationships as they struggle to establish an independent sense of self (Galanki & Christopoulos, 2011).

With respect to the personal fable, in a study of sixth through tenth graders, sense of omnipotence predicted self-esteem and overall positive adjustment. Viewing the self as highly capable and influential helps young people cope with challenges of adolescence. In contrast, sense of personal uniqueness was modestly associated with depression and suicidal thinking (Aalsma, Lapsley, & Flannery, 2006). Focusing on the distinctiveness of one's own experiences may interfere with forming close, rewarding relationships, which provide social support in stressful times. And when combined with a sensation-seeking personality, the personal fable seems to contribute to adolescent risk taking by reducing teenagers' sense of vulnerability (Alberts, Elkind, & Ginsberg, 2007). Young people with high personal-fable and sensation-seeking scores tend to take more sexual risks, more often use drugs, and commit more delinquent acts than their age-mates (Greene et al., 2000).

### Idealism and Criticism

Adolescents' capacity to think about possibilities opens up the world of the ideal. Teenagers can imagine alternative family, religious, political, and moral systems, and they want to explore them. They often construct grand visions of a world with no injustice, discrimination, or tasteless behavior. The disparity between teenagers' idealism and adults' greater realism creates tension between parent and child. Envisioning a perfect family against which their parents and siblings fall short, adolescents become fault-finding critics.

Overall, however, teenage idealism and criticism are advantageous. Once adolescents come to see other people as having both strengths and weaknesses, they have a much greater capacity to work constructively for social change and to form positive, lasting relationships (Elkind, 1994). Parents can help teenagers forge a better balance between the ideal and the real by tolerating

their criticism while reminding them that all people are blends of virtues and imperfections.

### Decision Making

Think back, once again, to evidence indicating that puberty triggers changes in the brain's emotional/social network that outpace development of the prefrontal cognitive-control network. Consequently, teenagers often perform less well than adults in decision making, where they must inhibit emotion and impulses in favor of thinking rationally.

Good decision making involves (1) recognizing the range of possible response options, (2) identifying pros and cons of each alternative, (3) assessing the likelihood of various outcomes, (4) evaluating one's choice in terms of whether one's goals were met and, if not, (5) learning from the mistake and making a better future decision. When researchers modified a card game to trigger strong emotion by introducing immediate feedback about gains and losses after each choice, teenagers behaved more irrationally, taking far greater risks than adults in their twenties (Figner et al., 2009). Additional evidence confirms that in decision-making contexts, adolescents—especially early adolescents—are far more enticed than adults are by the possibility of immediate reward (see page 373)—more willing to take risks and less likely to avoid potential losses (Christakou et al., 2013; Defoe et al., 2015).

Nevertheless, teenagers are less effective than adults at decision making even under “cool,” unemotional conditions (Huizenga, Crone, & Jansen, 2007). They less often carefully evaluate alternatives, instead falling back on well-learned intuitive judgments (Jacobs & Klaczynski, 2002). Consider a hypothetical problem requiring a choice, on the basis of two arguments, between taking a traditional lecture class and taking a computer-based class. One argument contains large-sample information: course evaluations from 150 students, 85 percent of whom liked the computer class. The other argument contains small-sample personal reports: complaints of two honor-roll students who both hated the computer class and enjoyed the traditional class (Klaczynski, 2001). Most adolescents, even those who knew that selecting the large-sample argument was “more intelligent,”

© JEFF GREENBERG/THE IMAGE WORKS

These high school students attending a college fair will face many choices over the next few years. But in making decisions, teenagers are less likely than adults to carefully weigh the pros and cons of each alternative.

based their choice on the small-sample argument, which resembled the informal opinions they depend on in everyday life.

Earlier we noted that processing skills governed by the prefrontal cognitive-control network, such as decision making, develop gradually. Like other aspects of cognitive development, decision making is affected by experience. As “first-timers” in many situations, adolescents do not have sufficient knowledge to consider pros and cons and predict likely outcomes. And after engaging in risky behavior without negative consequences, teenagers rate its benefits higher and its risks lower than peers who have not tried it (Halpern-Felsher et al., 2004). These faulty judgments increase the chances of continued risk taking.

Over time, young people learn from their successes and failures and gather information from others about factors that affect decision making (Reyna & Farley, 2006). School and community interventions that teach effective decision-making skills can help adolescents apply their capacity for metacognition by reflecting on and monitoring the decision process (Bruine de Bruin, 2012). But because taking risks without experiencing harmful outcomes can heighten adolescents’ sense of invulnerability, they need supervision and protection from high-risk experiences until their decision making improves.

## Ask yourself

**CONNECT** How does evidence on adolescent decision making help us understand teenagers’ risk taking in sexual activity and drug use?

**APPLY** Clarissa, age 14, is convinced that no one appreciates how hurt she feels at not being invited to the homecoming dance. Meanwhile, 15-year-old Justine, alone in her room, pantomimes being sworn in as student body president with her awestruck parents looking on. Which aspect of the personal fable is each adolescent displaying? Which one is more likely to be well-adjusted, and which poorly adjusted? Explain.

**REFLECT** Cite examples of your own idealistic thinking or poor decision making as a teenager. How has your thinking changed?

## Sex Differences in Mental Abilities

**11.16** What factors contribute to sex differences in mental abilities at adolescence?

Sex differences in mental abilities have sparked almost as much controversy as the ethnic and SES differences in IQ considered in Chapter 9. In most areas of cognitive functioning, including general intelligence, girls and boys are similar (Hyde, 2014). Still, they vary in certain specific mental abilities, most notably reading, writing, mathematical, and spatial skills.

### Verbal Abilities

Throughout the school years, girls attain higher scores in reading and writing achievement and account for a lower percentage of children referred for remedial reading instruction. Girls continue to score slightly higher on tests of verbal ability in middle childhood and adolescence in every country in which assessments have been conducted (Reilly, 2012; Wai et al., 2010). And when verbal tests are heavily weighted with writing, girls’ advantage is large (Halpern et al., 2007).

A special concern is that girls’ advantage in reading and writing achievement increases in adolescence, with boys doing especially poorly in writing—trends evident in the United States and other industrialized nations (Stoet & Geary, 2013; U.S. Department of Education, 2012a, 2016). These differences in literacy skills are believed to be major contributors to a widening gender gap in college enrollments. Whereas 40 years ago, males accounted for 60 percent of U.S. undergraduate students, today they are in the minority, at 44 percent (U.S. Department of Education, 2015).

Recall from Chapter 5 that girls have a biological advantage in earlier development of the left hemisphere of the cerebral cortex, where language is usually localized. And fMRI research indicates that in tackling language tasks (such as deciding whether two spoken or written words rhyme), 9- to 15-year-old girls show concentrated activity in language-specific brain areas. Boys, in contrast, display more widespread activation—in addition to language areas, considerable activity in auditory and visual areas, depending on how words are presented (Burman, Bitan, & Booth, 2008). This suggests that girls are more efficient language processors than boys, who rely heavily on sensory brain regions and process spoken and written words differently.

But girls also receive more verbal stimulation from early childhood through adolescence (Peterson & Roberts, 2003). Furthermore, children view language arts as a “feminine” subject. And as a result of the high-stakes testing movement, students today spend more time at their desks being taught in a regimented way—an approach particularly at odds with boys’ higher activity level, assertiveness, and incidence of learning problems. Clearly, reversing boys’ weakening literacy skills is a high priority, requiring a concerted effort by families, schools, and communities.

## Mathematical Abilities

Studies of mathematical abilities in the early school grades are inconsistent. Some find no disparities, others slight differences depending on the math skill assessed (Lachance & Mazzocco, 2006). Girls tend to be advantaged in counting, arithmetic computation, and mastery of basic concepts, perhaps because of their better verbal skills and more methodical approach to problem solving (Wei et al., 2012). But by late childhood to early adolescence, when math concepts become more abstract and spatial, boys outperform girls. The difference is especially evident on tests requiring complex reasoning (Lindberg et al., 2010; Reilly, Neumann, & Andrews, 2016). In science achievement, too, boys' advantage increases as problems become more difficult.

The male advantage is evident in most countries where boys and girls have equal access to secondary education. But the gap is typically small, varies considerably across nations, and has diminished over the past 30 years (Else-Quest, Hyde, & Linn, 2010; Halpern, 2012; Reilly, 2012). Among the most capable, however, the gender gap is larger. On average, twice as many twelfth-grade boys as girls attain very high math achievement scores—a difference that extends to science achievement as well (Reilly, Neumann, & Andrews, 2016; Wai et al., 2010).

Some researchers believe that heredity contributes to the gender gap in math, especially the tendency for more boys to be extremely talented. Accumulating evidence indicates that boys' advantage originates in two skill areas: (1) their more rapid numerical memory, which permits them to devote more working-memory resources to complex mental operations; and (2) their superior spatial reasoning, which enhances their mathematical problem solving (Halpern et al., 2007). Longitudinal evidence on nationally representative samples of U.S. high school students tracked for a decade or more reveals that high spatial ability in adolescence predicts subsequent advanced educational attainment in math-intensive fields and entry into science, technology, engineering, and math (STEM) careers, beyond the contributions of verbal and math ability (Wai, Lubinski, & Benbow, 2009). See the Biology and Environment box on pages 396–397 for further consideration of this issue.

Social pressures are also influential. Long before sex differences in math achievement appear, many children view math as a “masculine” subject. Also, parents typically think boys are better at it—an attitude that encourages girls to blame their errors on lack of ability and to consider math less useful for their future lives. These beliefs, in turn, reduce girls' confidence and interest in math and their willingness to consider STEM careers (Ceci & Williams, 2010; Kenney-Benson et al., 2006; Parker et al., 2012). Furthermore, *stereotype threat*—fear of being judged on the basis of a negative stereotype (see page 320 in Chapter 9)—causes girls to do worse than their

abilities allow on difficult math problems (Picho, Rodriguez, & Finnie, 2013). As a result of these influences, even girls who are highly talented are less likely to develop effective math reasoning skills.

A positive sign is that today, American boys and girls reach advanced levels of high school math and science study in equal proportions—a crucial factor in reducing sex differences in knowledge and skill (U.S. Department of Education, 2015). But boys spend more time than girls with screen media, and boys tend to use them differently—more often playing video games, creating Web pages, writing computer programs, analyzing data, and using graphics programs (Lenhart et al., 2010; Looker & Thiessen, 2003; Rideout, Foehr, & Roberts, 2010). As a result, boys acquire more specialized computer knowledge.

Clearly, extra steps must be taken to promote girls' interest in and confidence at math and science. As Figure 11.11 shows, in cultures that value gender equality, sex differences in math achievement are much smaller and, in two nations, reversed! Swedish and Icelandic high school girls exceed boys in math scores (Guiso et al., 2008; OECD, 2012). Similarly, math and science achievement gaps are smaller in countries with higher proportions of women in research-related professions, and in countries where few individuals view science as “masculine” (Else-Quest, Hyde, & Linn, 2010; Nosek et al., 2009; Reilly, 2012).

Finally, a math curriculum beginning in kindergarten that teaches children how to apply effective spatial strategies—

**FIGURE 11.11** Math achievement gender gaps in nine industrialized nations, arranged in order of increasing gender equality. Math achievement scores are based on 15-year-olds' performance on an identical test in each country. Country gender equality is a composite measure that includes cultural attitudes toward women, women's participation in the labor force and in politics and government, and women's educational attainment and economic opportunities. As country gender equality increases, boys' advantage in math achievement tends to decline; in Sweden and Iceland, girls' math scores exceed boys'. (Adapted from Guiso et al., 2008; OECD, 2012.)

## Biology and Environment

### Sex Differences in Spatial Abilities

Spatial skills are a key focus of researchers' efforts to explain sex differences in complex mathematical reasoning. The gender gap favoring males is large for *mental rotation tasks*, in which individuals must rotate a three-dimensional figure rapidly and accurately inside their heads (see Figure 11.10). Males also do considerably better on *spatial perception tasks*, in which people must determine spatial relationships by considering the orientation of the surrounding environment. Sex differences on *spatial visualization tasks*, involving analysis of complex visual forms, are weak or nonexistent. Because many strategies can be used to solve these tasks, both sexes may come up with effective procedures (Maeda & Yoon, 2013; Miller & Halpern, 2014).

Sex differences in spatial abilities emerge as early as the first few months of life, in male

**FIGURE 11.10** Types of spatial tasks. Large sex differences favoring males appear on mental rotation, and males do considerably better than females on spatial perception. In contrast, sex differences on spatial visualization are weak or nonexistent.

**Mental Rotation**

drawing diagrams, mentally manipulating visual images, searching for numerical patterns, and graphing—is vital (Nuttall, Casey, & Pezaris, 2005). Because girls are biased toward verbal processing, they may not attain their math and science potential unless they are specifically taught how to think spatially.

## Learning in School

**11.17** Discuss the impact of school transitions on adolescent adjustment.

**11.18** Discuss family, peer, school, and employment influences on academic achievement during adolescence.

**11.19** What factors increase the risk of high school dropout?

In complex societies, adolescence coincides with entry into secondary school. Most young people move into either a middle or a junior high school and then into a high school. With each change, academic achievement increasingly determines higher education options and job opportunities. In the following sections, we take up various aspects of secondary school life.

## School Transitions

When Sabrina started middle school, she left a small, intimate, self-contained sixth-grade classroom for a much larger school. “I don’t know most of the kids in my classes, and my teachers don’t know me,” Sabrina complained to her mother at the end of the first week. “Besides, there’s too much homework. I get assignments in all my classes at once. I can’t do all this!” she shouted, bursting into tears.

**Impact of School Transitions.** As Sabrina’s reactions suggest, school transitions can create adjustment problems. With each school change—from elementary to middle or junior high and then to high school—adolescents’ grades decline (Benner, 2011; Ryan, Shim, & Makara, 2013). The drop is partly due to tighter academic standards, but school transitions are also associated with reductions in achievement test scores and attendance, which cannot be explained by tougher grading (Benner & Wang, 2014; Schwerdt & West, 2013). The transition to secondary school often means less personal attention, more whole-class instruction, and less chance to participate in classroom decision making.

infants' superior ability to recognize a familiar object from a new perspective—a capacity requiring mental rotation (Moore & Johnson, 2011; Quinn & Liben, 2014). The male spatial advantage is present throughout childhood, adolescence, and adulthood in many cultures (Levine et al., 1999; Silverman, Choi, & Peters, 2007). One hypothesis is that heredity, perhaps through prenatal exposure to androgen hormones, underlies this finding. However, a large number of studies testing this idea have produced inconsistent findings (Hines, 2015). Although heredity likely plays a role, its path of influence remains unclear.

Growing evidence confirms that experience contributes to males' superior spatial performance. Children who engage in manipulative activities, such as block play, model building, and carpentry, do better on spatial tasks (Baenninger & Newcombe, 1995). Playing action video games enhances many cognitive processes important for spatial skills, including visual discrimination, speed of thinking, attention shifting, tracking of multiple objects, mental rotation, and wayfinding—gains that persist and generalize to diverse situations (Spence & Feng, 2010). Boys spend far more time than girls at these pursuits.

It is not surprising, then, that students often rate their middle and high school experiences less favorably than their elementary school experiences. They also report that their teachers care less about them, are less friendly, grade less fairly, and stress competition more. Consequently, many young people feel less academically competent, and their motivation and liking for school decline (Barber & Olsen, 2004; De Wit et al., 2011; Otis, Grouzet, & Pelletier, 2005).

Adolescents facing added strains—family disruption, poverty, low parent involvement, high parental conflict, low social support, or learned helplessness on academic tasks—at either transition are at greatest risk for self-esteem and academic difficulties (de Bruyn, 2005; De Wit et al., 2011; Seidman et al., 2003). Furthermore, the high school transition is especially challenging for African-American and Hispanic students who move to a new school with substantially fewer same-ethnicity peers (Benner & Graham, 2009). Under these conditions, minority adolescents report decreased feelings of belonging and school liking, and they show steeper declines in grades.

Distressed youths whose school performance either remains low or drops sharply after school transition often show a persisting pattern of poor self-esteem, motivation, and achievement. In

These teenagers take part in a science research competition for high school seniors. With supportive experiences, girls can excel in math and science.

Furthermore, adults seem to encourage spatial reasoning in boys more than girls, even during activities that are not gender typed. For example, when researchers observed preschoolers in their homes, boys and girls were equally likely to play with puzzles. But parents were more engaged and referred more often to spatial concepts with sons, who more often tackled difficult puzzles (Levine et al., 2012). Complex puzzle play predicted children's performance on a test of spatial abilities several months later.

Spatial skills respond readily to training, with improvements often larger than the sex differences themselves. But because boys and girls usually show similar training effects, sex differences typically persist (Uttal et al., 2013). In one study of first graders, however, training in mental rotation strategies over several months—a more intensive approach than previously tried—led girls to reach the same performance level as boys (Tzuriel & Egozi, 2010). This suggests that the right kind of early intervention can override genetically based sex differences in spatial skills.

another study, researchers compared “multiple-problem” youths (those having both academic and mental health problems), youths having difficulties in just one area (either academic or mental health), and well-adjusted youths (those doing well in both areas) across the transition to high school (Roeser, Eccles, & Freedman-Doan, 1999). Although all groups declined in grade point average, well-adjusted students continued to get high marks and multiple-problem youths low marks, with the others falling in between. In addition, the multiple-problem youths showed a far greater rise in truancy and out-of-school problem behaviors.

Adolescents with academic and emotional difficulties often turn to similarly alienated peers for the support they lack in other spheres of life (Rubin et al., 2013). For these vulnerable youths, the transition to high school may initiate a downward spiral in academic performance and school involvement that leads to failure and dropping out.

**Helping Adolescents Adjust to School Transitions.** As these findings reveal, school transitions often lead to environmental changes that fit poorly with adolescents' developmental needs (Eccles & Roeser, 2009). They disrupt close relationships with teachers at a time when adolescents need adult support.

SYRACUSE NEWSPAPERS/S. CANNIRELLI/THE IMAGE WORKS

On the first day of school, a teacher's caring attention helps this sixth grader deal with the stress of moving from a small, self-contained elementary school classroom to a large middle school.

They emphasize competition during a period of heightened self-focusing. They reduce decision making and choice as the desire for autonomy is increasing. And they interfere with peer networks as young people become more concerned with peer acceptance.

### LOOK and LISTEN

Ask several secondary school students to describe their experiences after school transition. What supports for easing the stress of transition did their teachers and school provide?

Support from parents, teachers, and peers can ease these strains (Waters, Lester, & Cross, 2014). Parental involvement, monitoring, gradual autonomy granting, and emphasis on mastery rather than merely good grades are associated with better adjustment (Gutman, 2006). Adolescents with close friends are more likely to sustain these friendships across the transition, which increases social integration and academic motivation in the new school (Aikens, Bierman, & Parker, 2005).

Some school districts reduce the number of school transitions by combining elementary and middle school into K–8 buildings. Compared with agemates who transition to middle school, K–8 sixth and seventh graders score higher in achievement (Kleffer, 2013; Schwerdt & West, 2013). Furthermore, teachers and administrators in K–8 buildings report more positive social contexts—less chaos, fewer conduct problems, and better overall working conditions (Kim et al., 2014). These factors predict students' favorable school attitudes, academically and socially.

Other less extensive changes are also effective. Forming smaller units within larger schools promotes closer relationships

with both teachers and peers along with greater extracurricular involvement (Seidman, Aber, & French, 2004). And a “critical mass” of same-ethnicity peers—according to one suggestion, at least 15 percent of the student body—helps teenagers feel socially accepted and reduces fear of out-group hostility (National Research Council, 2007). In the first year after a school transition, homerooms can be provided in which teachers offer academic and personal counseling. Assigning students to classes with several familiar peers or a constant group of new peers strengthens emotional security and social support. In schools that take these steps, students are less likely to decline in academic performance or display other adjustment problems (Felner et al., 2002).

## Academic Achievement

Adolescent achievement is the result of a long history of cumulative effects. Early on, positive educational environments, both family and school, lead to personal traits that support achievement—intelligence, confidence in one's own abilities, the desire to succeed, and high educational aspirations. Nevertheless, improving an unfavorable environment can foster resilience among poorly performing young people. See Applying What We Know on the following page for a summary of environmental factors that enhance achievement during the teenage years.

**Child-Rearing Styles.** Authoritative parenting is linked to higher grades and achievement test scores in school among adolescents varying widely in SES, just as it predicts mastery-oriented behavior in childhood (Collins & Steinberg, 2006; Pinquart, 2016). In contrast, authoritarian, permissive, and uninvolved styles are associated with poorer achievement and declines in academic performance over time.

The link between authoritative parenting and adolescents' academic competence has been confirmed in countries with diverse value systems, including Argentina, Australia, China, the Netherlands, Pakistan, and the United Kingdom (Chan & Koo, 2011; de Bruyn, Deković, & Meijnen, 2003; Steinberg, 2001). In Chapter 8, we noted that authoritative parents adjust their expectations to children's capacity to take responsibility for their own behavior. Warmth, open discussion, firmness, and monitoring of adolescents' whereabouts and activities make young people feel cared about and valued, encourage reflective thinking and self-regulation, and increase awareness of the importance of doing well in school. These factors, in turn, are related to mastery-oriented attributions, effort, achievement, and high educational aspirations (Gauvain, Perez, & Beebe, 2013; Gregory & Weinstein, 2004).

**Parent–School Partnerships.** In response to teenagers' desire for greater autonomy, parents' volunteering at school and contact with teachers tend to decline over adolescence. Nevertheless, high-achieving students typically have parents who remain invested in their teenager's education (Hill & Taylor, 2004). They keep tabs on academic progress, regularly attend parent–teacher conferences, make sure the young person is enrolled in challenging, well-taught classes, and emphasize the importance of doing well in school and engaging in academic planning.

## Applying what we Know

### Supporting High Achievement in Adolescence

FACTOR	DESCRIPTION
Child-rearing practices	Authoritative parenting Joint parent–adolescent decision making Parent involvement in the adolescent’s education
Peer influences	Peer valuing of and support for high achievement
School characteristics	Warm, supportive teachers who develop personal relationships with parents and show them how to support their teenager’s learning Learning activities that encourage high-level thinking Active student participation in learning activities and classroom decision making
Employment schedule	Job commitment limited to less than 15 hours per week High-quality vocational education for non-college-bound adolescents

In a large sample of U.S. tenth graders, students whose parents encouraged educational pursuits and high achievement more often completed homework on time, less often skipped class, and expressed greater interest and enjoyment in school learning (Wang & Sheikh-Khalil, 2014). When followed up nearly two years later, they gained in grade point average relative to age-mates with less involved parents, beyond the influence of SES and previous academic performance. Academically involved parents send a message to their youth about the value of education, model constructive solutions to academic problems, and promote wise educational decisions.

Compared to parents in neighborhoods with ample resources, parents in depleted, high-risk neighborhoods tend to report

higher levels of academic involvement with their teenagers at home. They seem to work harder at conveying to their children the value of education, even though daily stressors reduce their energy for such involvement (Bhargava & Witherspoon, 2015; Bunting et al., 2013). Yet stronger home–school links can relieve some of this stress. Schools can build parent–school partnerships by strengthening relationships between teachers and parents, organizing communities of parents who mutually support one another, and including parents in school governance so they remain aware of and invested in school goals.

**Peer Influences.** Peers play an important role in adolescent achievement, in a way that relates to both family and school. Teenagers whose parents value achievement generally choose friends who share those values (Kiuru et al., 2009; Rubin et al., 2013). For example, when Sabrina began to make new friends in middle school, she often studied with her girlfriends. Each girl wanted to do well and reinforced this desire in the others.

Peer support for high achievement also depends on the overall climate of the peer culture, which, for ethnic minority youths, is powerfully affected by the surrounding social order. In one study, integration into the school peer network predicted higher grades among European-American and Hispanic students but not among Asians and African Americans (Faircloth & Hamm, 2005). Asian cultural values stress respect for family and teacher expectations over close peer ties. African-American minority adolescents may observe that their ethnic group is worse off than the white majority in educational attainment, jobs, income, and housing. And discriminatory treatment by teachers and peers, often resulting from stereotypes that they are “not intelligent,” triggers anger, anxiety, self-doubt, declines in motivation and achievement, association with peers who are not interested in school, and increases in problem behaviors (Wong, Eccles, & Sameroff, 2003).

Schools that build close networks of support between teachers and peers can prevent these negative outcomes. One high school

While waiting for her husband to get off work, this mother helps her daughter with homework in front of a convenience store as her son plays nearby. Parents in depleted, high-risk neighborhoods work harder at conveying to their children the value of education, even though daily stressors reduce their energy for such involvement.

## Social Issues: Education

### Media Multitasking Disrupts Learning

“**M**om, I’m going to study for my biology test now,” called 16-year-old Ashley while shutting her bedroom door. Sitting down at her desk, she accessed a popular social media site on her laptop, donned headphones and began listening to a favorite song on her tablet, and placed her cell phone next to her elbow so she could hear it chime if any text messages arrived. Only then did she open her textbook and begin to read.

In a survey of a nationally representative sample of U.S. 8- to 18-year-olds, more than two-thirds reported engaging in two or more media activities at once, some or most of the time (Rideout, Foehr, & Roberts, 2010). When observed studying in their homes for just 15 minutes, adolescents diverted, on average, every 5 to 6 minutes to texting, social media sites, phone calling, or watching TV (Rosen, Carrier, & Cheever, 2013). The presence of a television in the young person’s bedroom is a strong predictor of this behavior, as is access to a mobile device—especially a smartphone. Nearly three-fourths of U.S. teenagers have smartphones, and one-fourth report being online “almost constantly” (Foehr, 2006; Pew Research Center, 2015g).

Research confirms that media multitasking greatly reduces learning. In one experiment, participants were given two tasks: learning to predict the weather in two different cities

using colored shapes as cues and keeping a mental tally of how many high-pitched beeps they heard through headphones. Half the sample performed the tasks simultaneously, the other half separately (Foerde, Knowlton, & Poldrack, 2006). Both groups learned to predict the weather in the two-city situation, but the multitaskers were unable to apply their learning to new weather problems.

fMRI evidence revealed that the participants working only on the weather task activated the hippocampus, which plays a vital role in *explicit memory*—conscious, strategic recall, which enables new information to be used flexibly and adaptively in contexts outside the original learning situation (see page 239 in Chapter 7). In contrast, the multitaskers activated subcortical areas involved in *implicit memory*—a shallower, automatic form of learning that takes place unconsciously.

Adolescents who often media multitask report problems with each aspect of executive function in everyday life—working memory (“I forget what I’m doing in the middle of things”), inhibition (“It’s hard for me to wait my turn”), and flexibly shifting attention (“I have trouble changing from one activity to another”) (Baumgartner et al., 2014). Consequently, beyond superficial preparation for her biology test, Ashley is likely to have difficulty concentrating and strategically

© LAURA DWIGHT PHOTOGRAPHY

Media multitasking while doing homework fragments attention, yielding superficial learning. Frequent multitaskers are likely to have trouble filtering out irrelevant stimuli even when they are not multitasking.

processing new information after turning off her electronic devices.

Experienced teachers often complain that compared to students of a generation ago, today’s teenagers are more easily distracted and learn less thoroughly. One teacher reflected, “It’s the way they’ve grown up—working short times on many different things at one time” (Clay, 2009, p. 40).

with a largely low-income ethnic minority student body (65 percent African American) reorganized into “career academies”—learning communities within the school, each offering a different career-related curriculum (for example, one focusing on health, medicine, and life sciences, another on computer technology). The vocationally relevant academic program combined with more caring teacher–student relationships helped create a school climate in which peers valued school engagement, collaborated on projects, and were motivated to do well academically (Conchas, 2006). High school graduation and college enrollment rates rose from a small minority to over 90 percent.

Finally, teenagers’ use of text messaging, e-mail, and social media sites to remain continuously in touch with peers—even

during class and while working on homework—is an aspect of contemporary peer-group life that poses risks to achievement. See the Social Issues: Education box above to find out about the impact of “media multitasking” on learning.

**School Characteristics.** Adolescents need school environments that are responsive to their expanding powers of reasoning and their emotional and social needs. Without appropriate learning experiences, their cognitive potential is unlikely to be realized.

**Classroom Learning Experiences.** As noted earlier, in large, departmentalized secondary schools, many adolescents report

that their classes lack warmth and supportiveness, which dampens their motivation. Of course, an important benefit of separate classes in each subject is that adolescents can be taught by experts, who are more likely to encourage high-level thinking, teach effective learning strategies, and emphasize content relevant to students' experiences—factors that contribute to interest, effort, and achievement (Crosnoe & Benner, 2015; Eccles, 2004). But many classrooms do not consistently provide stimulating, challenging teaching.

Wide variability in quality of instruction has contributed to increasing numbers of seniors who graduate from high school deficient in basic academic skills. Although the achievement gap separating African-American, Hispanic, and Native-American students from white students has declined since the 1970s, mastery of reading, writing, mathematics, and science by low-SES ethnic minority students remains disappointing (U.S. Department of Education, 2012a, 2012b, 2016). Too often these young people attend underfunded schools with rundown buildings, outdated equipment, and textbook shortages. In some, crime and discipline problems receive more attention than teaching and learning. By middle school, many low-SES minority students have been placed in low academic tracks, compounding their learning difficulties.

**Tracking.** Ability grouping, as we saw in Chapter 9, is detrimental during the elementary school years. At least into middle school, mixed-ability classes are desirable. They support the motivation and achievement of students varying widely in academic progress (Gillies, 2003; Gillies & Ashman, 1996).

By high school, some grouping is unavoidable because certain aspects of education must dovetail with the young person's future educational and vocational plans. In the United States, high school students are counseled into college preparatory, vocational, or general education tracks. Unfortunately, low-SES minority students are assigned in large numbers to noncollege tracks, perpetuating educational inequalities of earlier years.

Once assigned to a low academic track, students are “locked out” of advanced courses in later grades because they have not taken prerequisite courses, which restricts them to a lower-quality curriculum (Kelly & Price, 2011). Even in secondary schools with no formal tracking program, low-SES minority students tend to be assigned to lower course levels in most or all academic subjects, resulting in *de facto* (unofficial) *tracking* (Kalogrides & Loeb, 2013).

Breaking out of a low academic track is difficult, even when students try to do so. Interviews with African-American students revealed that many thought their previous performance did not reflect their ability. Yet teachers and counselors, overburdened with other responsibilities, had little time to reconsider individual cases (Ogbu, 2003). And compared to students in higher tracks, those in low tracks decline in academic self-esteem and exert substantially less effort—differences due in part to less stimulating classroom experiences and reduced teacher expectations (Chiu et al., 2008; Worthy, Hungerford-Kresser, & Hampton, 2009).

High school students are separated into academic and vocational tracks in virtually all industrialized nations. In China, Japan, and most Western European countries, students' placement is determined by a national exam, which usually establishes the young person's future possibilities. In the United States, students who are not assigned to a college preparatory track or who do poorly in high school can still attend college. Ultimately, however, many young people do not benefit from the more open U.S. system. By adolescence, SES differences in quality of education and academic achievement are greater in the United States than in most other industrialized countries. And the United States has a higher percentage of young people who see themselves as educational failures and drop out of high school (OECD, 2013c).

**Part-Time Work.** The number of U.S. high school students employed during the school year rises with age, from 40 percent of tenth graders to nearly 50 percent of twelfth graders—rates that exceed youth employment in other developed nations (Bachman, Johnston, & O'Malley, 2014). Most are middle-SES youths in pursuit of spending money rather than vocational exploration and training. Low-SES teenagers who need to contribute to family income or to support themselves find it harder to get jobs (Staff, Mont'Alvao, & Mortimer, 2015). But when African-American and Hispanic teenagers from economically disadvantaged homes are employed, they generally put in more work hours.

Adolescents typically hold jobs that involve low-level, repetitive tasks and provide little contact with adult supervisors. A heavy commitment to such jobs is harmful. The more hours students work, the poorer their school attendance, the lower their grades, the less likely they are to participate in extracurricular activities, and the more likely they are to drop out (Marsh & Kleitman, 2005). Students who spend many hours at such jobs also report more drug and alcohol use and delinquent acts (Monahan, Lee, & Steinberg, 2011; Samuolis et al., 2013). In contrast, steady, moderate hours of employment predict higher grades and greater likelihood of attending and completing college, especially among students who began high school with weak academic records (Staff & Mortimer, 2007). For these youths, perhaps paid work promotes effective time management, sense of responsibility, and self-confidence.

Work-study programs or other jobs that combine academic and vocational learning opportunities are also linked to favorable outcomes—positive school and work attitudes, improved academic performance, and reduced delinquency (Hamilton & Hamilton, 2000; Staff & Uggen, 2003). Yet high-quality vocational preparation for non-college-bound U.S. adolescents is scarce; just 6 percent of twelfth graders report participating in work-study programs (Bachman, Johnston, & O'Malley, 2014). Unlike some European nations, the United States has no widespread training system to prepare youths for skilled business and industrial occupations and manual trades. Although U.S. federal and state governments support some job-training programs, most are too brief to make a difference and serve too few young people in need of assistance.

## Dropping Out

Across the aisle from Louis in math class sat Norman, who daydreamed, crumpled his notes into his pocket after class, and rarely did his homework. On test days, he twirled a good luck charm but left most questions blank. Louis and Norman had been classmates since fourth grade, but they had little to do with each other. To Louis, who was quick at schoolwork, Norman seemed to live in another world. Once or twice a week, Norman cut class; one spring day, he stopped coming altogether.

Norman is one of about 7 percent of U.S. 16- to 24-year-olds who dropped out of high school and remain without a diploma or a GED (U.S. Department of Education, 2015). The overall dropout rate has declined since the mid-2000s, largely due to substantial gains in Hispanic teenagers' graduation rates. Nevertheless, as Figure 11.12 shows, dropout rates remain elevated among low-SES ethnic minority youths, especially Native-American and Hispanic teenagers. Also, boys drop out at considerably higher rates than girls.

The decision to leave school has dire consequences. Youths without upper secondary education have much lower literacy scores than high school graduates, and they lack the skills valued by employers in today's knowledge-based economy. Consequently, dropouts have much lower employment rates than high school graduates. Even when employed, dropouts are far more likely to remain in menial, low-paid jobs and to be out of work from time to time.

**Factors Related to Dropping Out.** Many dropouts show a persistent pattern of disruptive behavior combined with poor academic performance (Hawkins, Jaccard, & Needle, 2013). But others, like Norman, have few behavior problems; they simply experience academic difficulties and quietly disengage from school (Balfanz, Herzog, & MacIver, 2007). The pathway to dropping out starts early. Risk factors in first grade predict dropout nearly as well as risk factors in secondary school (Entwisle, Alexander, & Olson, 2005).

Norman—like other dropouts—had a long history of marginal-to-failing school grades and low academic self-esteem (Wexler & Pyle, 2013). As Norman got older, he attended class less regularly, paid little attention when he was there, and rarely did his homework. He didn't join school clubs or participate in sports. As a result, few teachers or students got to know him well. By the day he left, Norman felt alienated from all aspects of school life.

As with other dropouts, Norman's family background contributed to his problems. Compared with other students, even those with the same grade profile, dropouts are more likely to have parents who are uninvolved in their teenager's education and engage in little monitoring of their youngster's daily activities. Many are single parents, never finished high school themselves, and are unemployed (Pagani et al., 2008; Song, Benin, & Glick, 2012).

**FIGURE 11.12 U.S. high school dropout rates by ethnicity and gender.** Because many African-American, Hispanic, and Native-American young people come from economically disadvantaged families and attend underfunded, poor-quality schools, their dropout rates are above the national average. Rates for Native-American and Hispanic youths are especially high. Across all ethnicities, boys' dropout rates exceed girls' (Stark & Noel, 2015.)

Students who drop out often have school experiences that undermine their chances for success: grade retention, which marks them as academic failures; classes with unsupportive teachers and few opportunities for active participation; and frequent peer victimization (Brown & Rodriguez, 2009; Peguero, 2011). In such schools, rule breaking is common and often results in suspension, which—by excluding students from classes—contributes further to academic failure (Christie, Jolivet, & Nelson, 2007). Students in general education and vocational tracks, where teaching tends to be the least stimulating, are three times as likely to drop out as those in a college preparatory track (U.S. Department of Education, 2015). Boys' higher rates of learning and behavior problems from early childhood on contribute to their greater school leaving relative to girls.

**Prevention Strategies.** Among the diverse strategies available for helping teenagers at risk of dropping out, several common themes are related to success:

- *Supplementary academic instruction and counseling that offer personalized attention.* Most potential dropouts need intensive remedial instruction in small classes that permit warm, caring teacher–student relationships to form (Wilson & Tanner-Smith, 2013). In one successful approach, at-risk students are matched with retired adults, who serve as tutors, mentors, and role models in addressing academic and vocational needs (Prevatt, 2003).
- *High-quality vocational education.* For many marginal students, the real-life nature of vocational education is more comfortable and effective than purely academic work (Levin, 2012). To work well, vocational education must carefully integrate academic and job-related instruction so students see the relevance of classroom experiences to their future goals.

- *Efforts to address the many factors in students' lives related to leaving school early.* Programs that strengthen parent involvement, offer flexible work–study arrangements, and provide on-site child care for teenage parents can make staying in school easier for at-risk adolescents.
- *Participation in extracurricular activities.* Another way of helping marginal students is to draw them into the community life of the school. The most powerful influence on extracurricular involvement is small school size (Crosnoe, Johnson, & Elder, 2004; Feldman & Matjasko, 2007). As high school student body declines—dropping from 2,000 students to 500 to 700 students—at-risk youths are more likely to be needed to help staff activities. As a result, they feel more attached to their school. In large schools, creation of smaller “schools within schools” has the same effect.

Moderate (but not excessive) participation in arts, community service, or vocational development activities promotes diverse aspects of adjustment (Fredricks, 2012; Fredricks & Eccles, 2006). Among these are improved academic performance, reduced antisocial behavior, more favorable self-esteem and initiative, and increased peer acceptance.

As we conclude our discussion of academic achievement, let's place the school dropout problem in historical perspective. Over the second half of the twentieth century, the percentage of U.S. young people completing high school by age 24 increased steadily, from less than 50 percent to more than 90 percent. Although many dropouts get caught in a vicious cycle in which their lack of self-confidence and skills prevents them from seeking further education and training, of the 25 percent of high school freshmen who do not graduate on time, more than two-thirds return to finish their secondary education by their mid-twenties (U.S. Department of Education, 2015). And some extend their schooling further as they come to realize how essential education is for a rewarding job and a satisfying adult life.

A teenager receives additional academic support from a caring retired teacher—a successful strategy for preventing struggling students from dropping out of school.

## Ask yourself

**CONNECT** How are educational practices that prevent school dropout similar to those that improve learning for adolescents in general?

**APPLY** Tanisha is finishing sixth grade. She can either continue in her current school through eighth grade or switch to a much larger seventh- to ninth-grade middle school. Which choice would you suggest, and why?

**REFLECT** Describe your own experiences in making the transition to middle school and then to high school. What did you find stressful? What helped you adjust?

## Summary / chapter 11

### PHYSICAL DEVELOPMENT

#### Conceptions of Adolescence

(p. 368)

##### 11.1 How have conceptions of adolescence changed over the past century?

- **Adolescence** is the transition between childhood and adulthood. Early theorists viewed adolescence as either a biologically determined period of storm and stress or entirely influenced by the social environment. Contemporary researchers view adolescence as a joint product of biological, psychological, and social forces.
- In industrialized societies, adolescence is greatly extended.

#### Puberty: The Physical Transition to Adulthood (p. 368)

##### 11.2 Describe body growth, motor performance, and sexual maturation during puberty.

- Hormonal changes in middle childhood initiate **puberty**, on average, two years earlier for girls than for boys. As the body enlarges during the **growth spurt**, girls' hips and boys' shoulders broaden. Girls add more fat, boys more muscle.
- Puberty brings slow, gradual improvements in gross-motor performance for girls, dramatic gains for boys.

- At puberty, changes in **primary** and **secondary sexual characteristics** accompany rapid body growth. **Menarche** occurs late in the girl's sequence of pubertal events, after the growth spurt peaks. In boys, the peak in growth occurs later, preceded by enlargement of the sex organs and **spermarche**.

##### 11.3 What factors influence the timing of puberty?

- Heredity, nutrition, exercise, and overall physical health influence the timing of puberty. The emotional quality of family experiences may play a role.

- A **secular trend** toward earlier puberty has occurred in industrialized nations as physical well-being increased. In some countries, rising obesity rates have extended this trend.

#### 11.4 What changes in the brain take place during adolescence?

- Synaptic pruning in the cerebral cortex continues, and growth and myelination of stimulated neural fibers accelerates, strengthening connections within the brain, particularly those involving the prefrontal cortex. Consequently, adolescents gain in diverse cognitive skills, but gains are gradual, and self-regulation is not yet fully mature.
- Neurons become more responsive to excitatory neurotransmitters, heightening emotional reactivity and reward seeking. Changes in the brain's emotional/social network outpace development of the prefrontal cognitive-control network, resulting in difficulties controlling emotions and impulses.

- Revisions occur in brain regulation of sleep timing, leading to a sleep “phase delay.” Sleep deprivation contributes to poorer achievement, anxiety, irritability, depressed mood, and high-risk behaviors.

### The Psychological Impact of Pubertal Events (p. 374)

#### 11.5 Explain adolescents' reactions to the physical changes of puberty.

- Girls typically react to menarche with mixed emotions, although those who receive advance information and support from family members respond more positively. Boys, who receive little social support for pubertal changes, react to spermarche with mixed feelings.
- Besides higher hormone levels, negative life events and adult-structured situations are associated with adolescents' negative moods. Psychological distancing between parent and child at puberty may be a modern substitute for physical departure from the family.

#### 11.6 Describe the impact of pubertal timing on adolescent adjustment, noting sex differences.

- Early-maturing boys and late-maturing girls have a more positive **body image** and usually adjust well. In contrast, early-maturing girls and late-maturing boys tend to experience emotional and social difficulties, which—for girls—persist into early adulthood.

### Health Issues (p. 378)

#### 11.7 Describe nutritional needs during adolescence, and cite factors related to eating disorders.

- Nutritional requirements increase with rapid body growth, and vitamin and mineral deficiencies may result from poor eating habits. Frequency of family meals is associated with healthy eating.
- Early puberty, certain personality traits, maladaptive family interactions, and societal emphasis on thinness heighten risk of eating disorders such as **anorexia nervosa**, **bulimia nervosa**, and **binge-eating disorder**. Heredity also plays a role.

#### 11.8 Discuss social and cultural influences on adolescent sexual attitudes and behavior.

- North American attitudes toward adolescent sex are relatively restrictive. Parents and the mass media deliver contradictory messages.
- Early, frequent sexual activity is linked to factors associated with economic disadvantage. Adolescent cognitive processes and weak social supports for responsible sexual behavior underlie the failure of many sexually active teenagers to practice contraception consistently.

#### 11.9 Cite factors involved in development of sexual orientation.

- Biological factors, including heredity and prenatal hormone levels, play an important role in sexual orientation. Lesbian, gay, and bisexual teenagers face special challenges in establishing a positive sexual identity.

#### 11.10 Discuss factors related to sexually transmitted infections and teenage pregnancy and parenthood, noting prevention and intervention strategies.

- Early sexual activity, combined with inconsistent contraceptive use, results in high rates of sexually transmitted infections (STIs) among U.S. adolescents.
- Life conditions linked to poverty and personal attributes jointly contribute to adolescent child-bearing. Teenage parenthood is associated with school dropout, reduced chances of marriage, greater likelihood of divorce, and long-term economic disadvantage.

- Effective sex education, access to contraceptives, and programs that build academic and social competence help prevent early pregnancy. Adolescent mothers need school programs that provide job training, instruction in life-management skills, and child care. When teenage fathers stay involved, children develop more favorably.

#### 11.11 What personal and social factors are related to adolescent substance use and abuse?

- Teenage alcohol and drug use is pervasive in industrialized nations. Drug taking reflects adolescent sensation seeking and drug-dependent cultural contexts. The minority who move to substance abuse tend to start using drugs early and to have serious personal, family, school, and peer problems.
- Effective prevention programs work with parents early to reduce family adversity, strengthen parenting skills, and build teenagers' competence.

## COGNITIVE DEVELOPMENT

### Piaget's Theory: The Formal Operational Stage (p. 388)

#### 11.12 What are the major characteristics of formal operational thought?

- In Piaget's **formal operational stage**, adolescents become capable of **hypothetico-deductive reasoning**. To solve problems, they form a hypothesis; deduce logical, testable inferences; and systematically isolate and combine variables to see which inferences are confirmed.

- Adolescents also develop **propositional thought**—the ability to evaluate the logic of verbal statements without referring to real-world circumstances.

#### 11.13 Discuss follow-up research on formal operational thought and its implications for the accuracy of Piaget's formal operational stage.

- Individuals are most likely to think abstractly and systematically in situations in which they have had extensive guidance and practice. Learning activities in school provide adolescents with rich opportunities to acquire formal operations. Gains occur gradually rather than as a sudden stage shift.

## An Information-Processing View of Adolescent Cognitive Development (p. 390)

### 11.14 How do information-processing researchers account for cognitive changes in adolescence?

- Information-processing researchers believe that a variety of specific mechanisms underlie cognitive gains in adolescence: increased working memory, improved inhibition, more selective and flexible attention, improved planning, more effective strategies, increased knowledge, expanded metacognition, and improved cognitive self-regulation.
- Scientific reasoning—the ability to coordinate theory with evidence—improves as adolescents solve increasingly complex problems and acquire more sophisticated metacognitive understanding.

## Consequences of Adolescent Cognitive Changes (p. 392)

### 11.15 Describe typical reactions of adolescents that result from their advancing cognition.

- As adolescents reflect on their own thoughts, two distorted images of the relation between self and other appear—the **imaginary audience** and the **personal fable**. Both result from heightened social sensitivity and gains in perspective taking.

© DOCO DALFIANO/ROBERT HARDING

- Adolescents' capacity to think about possibilities prompts idealistic visions at odds with reality, and teenagers often become fault-finding critics.
- Adolescents are less effective at decision making than adults. They take greater risks in emotionally charged situations, less often weigh alternatives, and more often fall back on intuitive judgments.

## Sex Differences in Mental Abilities (p. 394)

### 11.16 What factors contribute to sex differences in mental abilities at adolescence?

- Girls' advantage in reading and writing achievement increases, probably due to more efficient language processing and greater verbal stimulation. Gender stereotyping of language arts as "feminine" and regimented teaching may weaken boys' literacy skills.
- By early adolescence, when concepts become more abstract and spatial, boys surpass girls in mathematical performance. Overall, the gender difference is small, but it is larger among the most capable. Boys' superior spatial reasoning enhances their mathematical problem solving. Americans' gender stereotyping of math as "masculine" contributes to boys' greater self-confidence and interest in pursuing STEM careers.

## Learning in School (p. 396)

### 11.17 Discuss the impact of school transitions on adolescent adjustment.

- School transitions bring larger, more impersonal school environments, in which grades and feelings of competence decline. Teenagers coping with added stressors are at greatest risk for self-esteem and academic problems.

### 11.18 Discuss family, peer, school, and employment influences on academic achievement during adolescence.

- Authoritative parenting and parents' school involvement promote high achievement. Teenagers whose parents value achievement generally choose friends who share those values. Schools can help by promoting a peer culture that values school engagement.

© LAURA DWIGHT PHOTOGRAPHY

- Warm, supportive classroom environments that encourage student interaction and high-level thinking enable adolescents to reach their academic potential.
- By high school, separate educational tracks that dovetail with students' future plans are necessary. However, U.S. high school tracking usually extends the educational inequalities of earlier years.
- Steady, moderate hours of part-time employment predict higher grades and greater likelihood of attending and completing college. But a heavy commitment to low-level jobs with little adult supervision can impair school attendance, academic performance, and extracurricular participation.

### 11.19 What factors increase the risk of high school dropout?

- Factors related to dropping out include lack of parental support for achievement, a history of poor school performance, classes with unsupportive teachers, and frequent peer victimization.

## Important Terms and Concepts

adolescence (p. 367)  
 anorexia nervosa (p. 378)  
 binge-eating disorder (p. 379)

# chapter 12

AKGCF/ALAMY

## Emotional and Social Development in Adolescence

As adolescents spend less time with family members, peer groups become more tightly knit into cliques. Mixed-sex cliques prepare teenagers for dating by providing models of how to interact and opportunities to do so without having to be intimate.

### Peer Relations

Friendships • Cliques and Crowds • Dating

### Problems of Development

Depression • Suicide • Delinquency

■ **BIOLOGY AND ENVIRONMENT** Two Routes to Adolescent Delinquency

Louis sat on the grassy hillside overlooking the high school, waiting for his best friend, Darryl, to arrive. The two boys often had lunch together. Watching as hundreds of students poured onto the school grounds, Louis reflected on what he had learned in government class that day:

“Suppose I *had* been born in the People’s Republic of China. I’d be sitting here, speaking a different language, being called by a different name, and thinking about the world in different ways. Wow,” Louis pondered. “I am who I am through some quirk of fate.”

Louis awoke from his thoughts with a start to see Darryl standing in front of him. “Hey, dreamer! I’ve been shouting and waving from the bottom of the hill for five minutes. How come you’re so spaced out lately, Louis?”

“Oh, just wondering about stuff—what I want, what I believe in. My older brother Jules—I envy him. He seems to know more about where he’s going. I’m up in the air about it. You ever feel that way?”

“Yeah, a lot,” Darryl admitted, looking at Louis seriously. “I wonder, what am I really like? Who will I become?”

Louis and Darryl’s introspective remarks are signs of a major reorganization of the self at adolescence: the development of identity. Both young people are attempting to formulate who they are—their personal values and the directions they will pursue in life. The restructuring of the self that begins in adolescence is profound. Rapid physical changes prompt teenagers to reconsider what they are like as people. And the capacity to think hypothetically enables them to project themselves into the distant future. They start to realize the significance of their choice of values, beliefs, and goals for their later lives.

We begin this chapter with Erikson’s account of identity development and the research it has stimulated on teenagers’ thoughts and feelings about themselves. The quest for identity extends to many aspects of development. We will see how a sense of cultural belonging and moral understanding are refined during adolescence. And as parent-child relationships are revised and young people become increasingly independent of the family, friendships and peer networks become crucial contexts for bridging the gap between childhood and adulthood. Our chapter concludes with a discussion of several serious adjustment problems of adolescence: depression, suicide, and delinquency. ●

## Erikson's Theory: Identity versus Role Confusion

**12.1** According to Erikson, what is the major personality attainment of adolescence?

Erikson (1950, 1968) was the first to recognize **identity** as the major personality attainment of adolescence and as a crucial step toward becoming a productive, content adult. Constructing an identity involves defining who you are, what you value, and the directions you choose to pursue in life. One expert described it as an explicit theory of oneself as a rational agent—one who acts on the basis of reason, takes responsibility for those actions, and can explain them (Moshman, 2011). This search for what is true and real about the self drives many choices—vocation, interpersonal relationships, community involvement, ethnic-group membership, and expression of one's sexual orientation, as well as moral, political, and religious ideals.

Although the seeds of identity formation are planted early, not until late adolescence and early adulthood do young people become absorbed in this task. According to Erikson, in complex societies, young people often experience an *identity crisis*—a temporary period of distress as they experiment with alternatives before settling on values and goals. They go through a process of inner soul-searching, sifting through characteristics that defined the self in childhood and combining them with emerging traits, capacities, and commitments. Then they mold these into a solid inner core that provides a mature identity—a sense of self-continuity as they move through various roles in daily life. Once formed, identity continues to be refined in adulthood as people reevaluate earlier commitments and choices.

Erikson called the psychological conflict of adolescence **identity versus role confusion**. He believed that successful psychosocial outcomes of infancy and childhood pave the way toward a positive resolution. If young people's earlier conflicts were resolved negatively or if society limits their choices to ones that do not match their abilities and desires, they are likely to appear shallow, directionless, and unprepared for the challenges of adulthood.

Current theorists agree with Erikson that questioning of values, plans, and priorities is necessary for a mature identity, but they no longer describe this process as a "crisis." In fact, Erikson himself did not believe that the adolescent's inner struggle need be severe to form a clear, unified identity (Kroger, 2012). For most young people, identity development is not traumatic and disturbing but, rather, a process of *exploration* followed by *commitment*. As young people try out life possibilities, they gather important information about themselves and their environment and move toward making enduring decisions (Moshman, 2011). In the following sections, we will see that adolescents go about the task of defining the self in ways that closely match Erikson's description.

## Self-Understanding

**12.2** Describe changes in self-concept and self-esteem during adolescence.

**12.3** Describe the four identity statuses, along with factors that promote identity development.

During adolescence, the young person's vision of the self becomes more complex, well-organized, and consistent. Compared with children, adolescents engage in evaluations of an increasing variety of aspects of the self. Over time, they construct a balanced, integrated representation of their strengths and limitations (Harter, 2012). Changes in self-concept and self-esteem set the stage for developing a unified personal identity.

### Changes in Self-Concept

Recall that by the end of middle childhood, children describe themselves in terms of personality traits. In early adolescence, they unify separate traits ("smart" and "curious") into more abstract descriptors ("intelligent"). But these generalizations are not interconnected and are often contradictory. For example, 12- to 14-year-olds might mention opposing traits—"intelligent" and "clueless," "extrovert" and "introvert." These disparities result from the expansion of adolescents' social world, which creates pressure to display different selves in different relationships. As adolescents' awareness of these inconsistencies grows, they frequently agonize over "which is the real me" (Harter, 2012).

By late adolescence, cognitive changes enable teenagers to combine their traits into an organized system. Their use of qualifiers ("I have a *fairly* quick temper," "I'm not *thoroughly* honest") reveals an increasing awareness that psychological qualities can vary from one situation to the next. Older adolescents also add integrating principles that make sense of formerly troublesome contradictions. "I'm very adaptable," said one young person. "When I'm around my friends, who think what I say is important, I'm talkative; but around my family I'm quiet because they're never interested enough to really listen to me" (Damon, 1990, p. 88).

Compared with school-age children, teenagers place more emphasis on social virtues, such as being friendly, considerate, kind, and cooperative—traits that reflect adolescents' increasing concern with being viewed positively by others. Among older adolescents, personal and moral values also appear as key themes. As young people revise their views of themselves to include enduring beliefs and plans, they move toward the unity of self that is central to identity development.

### Changes in Self-Esteem

Self-esteem, the evaluative side of self-concept, continues to differentiate in adolescence. Teenagers add several new dimensions of self-evaluation—close friendship, romantic appeal, and job

competence—to those of middle childhood (see Chapter 10, pages 337–338) (Harter, 2012).

Level of general self-esteem also changes. Though some adolescents experience temporary or persisting declines after school transitions (see Chapter 11, page 397), self-esteem rises from mid- to late adolescence for most young people, who report feeling especially good about their peer relationships, physical appearance, and athletic capabilities (Birkeland et al., 2012; Cole et al., 2001; Impett et al., 2008). Teenagers often assert that they have become more mature, capable, personable, and attractive. In longitudinal research on a nationally representative sample of U.S. youths, an increasing sense of mastery—feeling competent and in control of one’s life—strongly predicted this rise in self-esteem (Erol & Orth, 2011). With greater independence and opportunities to emphasize pursuits in which they experience success, older adolescents are better able to discount the importance of doing well in areas in which they feel inadequate.

Teenagers with mostly favorable self-esteem profiles tend to be well-adjusted, whereas low self-esteem in all areas is linked to adjustment difficulties. But certain self-esteem factors are more strongly related to well-being. Adolescents with poor academic self-esteem tend to be anxious and unfocused, and those with negative peer relationships are likely to be anxious and depressed (Marsh, Parada, & Ayotte, 2004; Rudolph, Caldwell, & Conley, 2005).

What factors influence self-esteem? In Chapter 11, we saw that adolescents who are off time in pubertal development, who

are heavy drug users, and who fail in school feel poorly about themselves. And as in middle childhood, adolescent girls score lower than boys in overall sense of self-worth, though the difference remains slight (Bachman et al., 2011; Shapka & Keating, 2005). Recall that girls feel less positively about their physical appearance and athletic skills and less competent at math and science (see Chapter 10). At the same time girls continue to out-score boys on self-esteem dimensions of language arts, close friendship, and social acceptance.

But the contexts in which young people find themselves can modify these group differences. Authoritative parenting continues to predict stable, favorable self-esteem, as does encouragement from teachers (Lindsey et al., 2008; McKinney, Donnelly, & Renk, 2008; Wilkinson, 2004). In contrast, teenagers whose parents are critical and insulting have highly unstable and generally low self-esteem (Kernis, 2002). Peer acceptance can have a protective effect on general self-esteem for teenagers experiencing low parental warmth and approval (Birkeland, Breivik, & Wold, 2014). But adolescents exposed to highly negative parental feedback tend to rely excessively on peers to affirm their self-worth—a risk factor for adjustment difficulties (DuBois et al., 1999, 2002).

The larger social environment also influences self-esteem. Sustaining a middle-childhood trend, European-American adolescents’ self-esteem is less positive than that of African-American teenagers, who may benefit from greater extended family support and ethnic pride (Gray-Little & Hafdahl, 2000). And Asians score lower in self-esteem relative to European Americans as adolescence progresses—a decline reflecting cultural valuing of modesty and disapproval of boastfulness rather than sense of personal competence (Bachman et al., 2011). Finally, teenagers who attend schools or live in neighborhoods where their ethnic group is well-represented have fewer self-esteem problems (Gray-Little and Carels, 1997).

## Paths to Identity

Adolescents’ well-organized self-descriptions and differentiated sense of self-esteem provide the cognitive foundation for forming an identity. Using a clinical interviewing procedure devised by James Marcia (1980) or briefer questionnaire measures, researchers commonly evaluate progress in identity development on two key criteria derived from Erikson’s theory: *exploration* and *commitment*. Their various combinations yield four *identity statuses*, summarized in Table 12.1: **identity achievement**, commitment to values and goals following a period of exploration; **identity moratorium**, exploration without having reached commitment; **identity foreclosure**, commitment in the absence of exploration; and **identity diffusion**, characterized by lack of both exploration and commitment.

Identity development follows many paths. Some young people remain in one status, whereas others experience multiple status transitions. And the pattern often varies across *identity domains*, such as sexual orientation, vocation, and religious and political values. When assessed periodically between the mid-teens and mid-twenties, many young people change from “lower”

© DAVID R. FRAZIER/THE IMAGE WORKS

From mid- to late adolescence, self-esteem typically rises, fostered by pride in new competencies and growing self-confidence. This teenager beams as she displays the blue ribbon she won at an agricultural fair.

**TABLE 12.1**  
**The Four Identity Statures**

IDENTITY STATUS	DESCRIPTION	EXAMPLE
Identity achievement	Having explored alternatives, identity-achieved individuals are committed to clearly formulated self-chosen values and goals. They feel a sense of psychological well-being, of sameness through time, and of knowing where they are going.	When asked about her willingness to give up pursuing her chosen occupation if something better came along, Lauren responded, “Well, I might, but I doubt it. I’ve thought long and hard about law as a career. I’m pretty certain it’s for me.”
Identity moratorium	<i>Moratorium</i> means “delay or holding pattern.” These individuals have not yet made definite commitments. They are in the process of exploring—gathering information and trying out activities, with the desire to find values and goals to guide their lives.	When asked whether he had ever had doubts about his religious beliefs, Ramón said, “Yes, I guess I’m going through that right now. I just don’t see how there can be a God and yet so much evil in the world.”
Identity foreclosure	Identity-foreclosed individuals have committed themselves to values and goals without exploring alternatives. They accept a ready-made identity chosen for them by authority figures—usually parents but sometimes teachers, religious leaders, or romantic partners.	When asked if she had ever reconsidered her political beliefs, Emily answered, “No, not really, our family is pretty much in agreement on these things.”
Identity diffusion	Identity-diffused individuals lack clear direction. They are not committed to values and goals, nor are they actively trying to reach them. They may never have explored alternatives or may have found the task too threatening and overwhelming.	When asked about his attitude toward nontraditional gender roles, Justin responded, “Oh, I don’t know. It doesn’t make much difference to me. I can take it or leave it.”

statuses (foreclosure or diffusion) to higher ones (moratorium or achievement), but nearly as many remain stable, and some move in the reverse direction (Kroger, 2012; Kroger, Martinussen, & Marcia, 2010; Meeus et al., 2010).

The process of identity formation typically involves exploring a range of alternatives, making provisional commitments, engaging in in-depth evaluation of one’s choices, and—if those choices fit poorly with one’s capacities and potentials—refocusing on possible alternative commitments (Crocetti & Meeus, 2015; Luyckx et al., 2011). Consequently, young people often cycle between in-depth exploration and reconsideration—which can involve intense uncertainty and, thus, temporary diffusion—before eventually arriving at enduring commitments.

Because attending college offers expanded opportunities to explore values, career options, and lifestyles, college students usually make more identity progress than they did in high school (Klimstra et al., 2010; Montgomery & Côté, 2003). After college, many young people continue to sample a broad range of life experiences before making clear commitments. Those who go to work immediately after high school graduation generally settle on a self-definition earlier. But if non-college-bound youths encounter obstacles to realizing their occupational goals because of lack of training or vocational choices, they are at risk for identity foreclosure or diffusion (Eccles et al., 2003).

With respect to gender, some girls show more sophisticated reasoning than boys in identity domains related to intimacy, such as sexuality and family versus career priorities. Otherwise, consistent with Erikson’s psychosocial stages (see page 15 in Chapter 1), adolescents of both sexes typically make progress on identity concerns before experiencing genuine intimacy in romantic relationships (Arseth et al., 2009; Beyers & Seiffge-Krenke, 2010).

## Identity Status and Psychological Well-Being

A wealth of research verifies that both identity achievement and moratorium are psychologically healthy routes to a mature self-definition. Long-term foreclosure and diffusion, in contrast, are maladaptive.

Although young people in moratorium are at times anxious and depressed about finding commitments, they resemble identity-achieved individuals in using an active, *information-gathering cognitive style* to make personal decisions and solve problems: They seek out relevant information, evaluate it carefully, and critically reflect on their views (Berzonsky, 2011). Individuals who are identity-achieved or exploring tend to have higher self-esteem, are more open to alternative ideas and values, feel more in control of their lives, are more likely to view school and work as feasible avenues for realizing their aspirations, and are more advanced in moral reasoning and more concerned with social justice (Berzonsky et al., 2011; Crocetti et al., 2013). But an exception to these favorable outcomes exists: If exploration becomes ruminative—excessively concerned with making the right choice so the young person makes no choice at all—it is associated with distress and poor adjustment (Beyers & Luyckx, 2016).

Because foreclosure involves commitment, it offers a sense of security in the face of important life choices (Meeus et al., 2012). Although typically low in anxiety and highly satisfied with life, foreclosed individuals display a *dogmatic, inflexible cognitive style*, internalizing the values and beliefs of parents and others without deliberate evaluation and resisting information that threatens their position (Berzonsky, 2011; Berzonsky et al., 2011). Most fear rejection by people on whom they depend for affection and

self-esteem. A few foreclosed teenagers who are alienated from their families and society may join cults or other extremist groups, uncritically adopting a way of life different from their past.

Long-term diffused individuals are the least mature in identity development. They typically use a *diffuse-avoidant cognitive style* in which they avoid dealing with personal decisions and problems and, instead, allow current situational pressures to dictate their reactions (Berzonsky, 2011; Crocetti et al., 2013). Taking an “I don’t care” attitude, they entrust themselves to luck or fate and tend to go along with the crowd. As a result, they often experience time management and academic difficulties, are low in self-esteem and prone to depression, and, of all young people, are the most likely to commit antisocial acts and to use and abuse drugs (Meeus et al., 2012). Often at the heart of their apathy is a sense of hopelessness about the future.

## Influences on Identity Development

Adolescent identity formation begins a lifelong, dynamic process in which a change in either the individual or the context opens up the possibility of reformulating identity. A wide variety of factors influence identity development.

Identity status, as we have just seen, is both cause and consequence of personality characteristics. Adolescents who assume that absolute truth is always attainable tend to be foreclosed, while those who doubt that they will ever feel certain about anything are more often identity-diffused. Young people who are curious, open-minded, and persistent in the face of obstacles, and who appreciate that they can use rational criteria to choose among alternatives, are likely to be in a state of moratorium or identity achievement (Berzonsky et al., 2011; Schwartz et al., 2013).

Identity development is enhanced when families serve as a “secure base” from which adolescents can confidently move out into the wider world. Young people who feel attached to their parents but also free to voice their own opinions tend to have committed to values and goals and are on their way to identity achievement (Crocetti et al., 2014; Luyckx, Goossens, & Soenens, 2006). Foreclosed teenagers often have close bonds with parents

but lack opportunities for healthy separation. And diffused young people report the lowest levels of parental support and of warm, open communication (Arseth et al., 2009).

Interaction with diverse peers through school and community activities encourages adolescents to explore values and role possibilities (Barber et al., 2005). And close friends, like parents, can act as a secure base, providing emotional support, assistance, and models of identity development. In one study, 15-year-olds with warm, trusting peer ties were more involved in exploring relationship issues (Meeus, Oosterwegel, & Vollebergh, 2002). They thought seriously about what they valued in close friends and in a life partner.

Identity development also depends on schools and communities that offer rich and varied opportunities for exploration. Supportive experiences include classrooms that promote high-level thinking, teachers and counselors who encourage low-SES and ethnic minority students to go to college, elective classes and extracurricular and community activities that enable teenagers to pursue their interests and talents, and vocational training that immerses adolescents in the real world of adult work (Hardy et al., 2011; McIntosh, Metz, & Youniss, 2005; Sharp et al., 2007).

Culture strongly influences an aspect of mature identity not captured by the identity-status approach: constructing a sense of self-continuity despite significant personal changes. In one study, researchers asked Native Canadian and cultural-majority 12- to 20-year-olds to describe themselves in the past and in the present and then to justify why they regarded themselves as the same continuous person (Lalonde & Chandler, 2005). Most cultural-majority adolescents used an individualistic approach: They described an *enduring personal essence*, a core self that remained the same despite change. In contrast, Native Canadian youths took an interdependent approach that emphasized a *constantly transforming self*, resulting from new roles and relationships. They typically constructed a *coherent narrative* in which they linked together various time slices of their life with a thread that explained how they had changed in meaningful ways.

Finally, societal forces also are responsible for the special challenges faced by lesbian, gay, and bisexual youths (see Chapter 11) and by ethnic minority adolescents in forming a secure identity (see the Cultural Influences box on page 412). Applying What We Know on page 413 summarizes ways that adults can support adolescents in their quest for identity.

An internship in a veterinary office enables this teenager to explore a real-world career related to her love of animals, thereby fostering identity development.

## Ask yourself

**CONNECT** Explain the close link between adolescent identity development and cognitive processes.

**APPLY** Return to the conversation between Louis and Darryl in the opening of this chapter. Which identity status best characterizes each of the two boys, and why?

**REFLECT** Does your identity progress vary across the domains of sexuality, close relationships, vocation, religious beliefs, and political values? Describe factors that may have influenced your identity development in an important domain.

## Cultural Influences

### Identity Development Among Ethnic Minority Adolescents

For teenagers who are members of minority groups, **ethnic identity**—a sense of ethnic-group membership and the attitudes, beliefs, and feelings associated with that membership—is central to the quest for identity. As minority youths develop cognitively and become more sensitive to feedback from the social environment, they become painfully aware of how their ethnicity and race compromise their life chances. This discovery complicates their efforts to develop a sense of cultural belonging and a set of personally meaningful goals.

In many immigrant families from cultures that value interdependent qualities, adolescents' commitment to obeying their parents and fulfilling family obligations lessens the longer the family has been in the immigrant-receiving country. This circumstance induces **acculturative stress**—psychological distress resulting from conflict between the minority and the host culture (Phinney, Ong, & Madden, 2000). When immigrant parents tightly restrict their teenagers through fear that assimilation into the larger society will undermine their cultural traditions, their youngsters often rebel, rejecting aspects of their ethnic background.

At the same time, discrimination can interfere with the formation of a positive ethnic identity. In one study, Mexican-American youths who had experienced more discrimination were less likely to explore their ethnicity (Romero & Roberts, 2003). Those with low ethnic pride showed a sharp drop in self-esteem in the face of discrimination.

With age, many minority young people strengthen their ethnic identity. But because the process of forging an ethnic identity can be painful and confusing, others show no change, and still others regress (Huang & Stormshak, 2011). Young people with parents of different ethnicities face extra challenges. In a large survey of high school students, part-black biracial teenagers reported as much discrimination as their monoracial black counterparts, yet they felt less positively about their ethnicity. And compared with monoracial minorities, many biracial adolescents—including black-white,

black-Asian, white-Asian, black-Hispanic, and white-Hispanic—regarded their ethnicity as less central to their identities (Herman, 2004). Perhaps these adolescents encountered fewer opportunities in their homes and communities to forge a strong sense of belonging to either culture.

Adolescents whose family members encourage them to disprove ethnic stereotypes of low achievement or antisocial behavior typically surmount the threat that discrimination poses to a favorable ethnic identity. These young people manage experiences of unfair treatment effectively, by seeking social support and engaging in direct problem solving (Scott, 2003). Also, minority adolescents whose families have taught them the history, traditions, values, and language of their ethnic group are more likely to explore and progress toward ethnic identity achievement (Douglass & Umaña-Taylor, 2015; Else-Quest & Morse, 2015).

Interacting with same-ethnicity peers is also vital. Ethnic identity progress tends to be similar among same-ethnicity friends, and it can be predicted by the frequency with which they talk about ethnic and racial issues (Syed & Juan, 2012). In a study of Asian-American adolescents, contact with other Asians strengthened positive feelings about their own ethnic group in a mostly white or a racially mixed school but not in a mostly Asian school (Yip, Douglass, & Shelton, 2013). Ethnic identity concerns become especially salient in racially diverse settings.

How can society help minority adolescents resolve identity conflicts constructively? Here are some relevant approaches:

- Promote effective parenting, in which children and adolescents benefit from family ethnic pride yet are encouraged to explore the meaning of ethnicity in their own lives.

Adolescents of the Iroquois Tuscarora tribe perform a traditional dance at the New York State Fair. Minority youths whose cultural heritage is respected in their communities are more likely to develop a strong, secure ethnic identity.

- Ensure that schools respect minority youths' native languages and right to high-quality education.
- Foster contact with peers of the same ethnicity, along with respect between ethnic groups.

A strong, secure ethnic identity is associated with higher self-esteem, optimism, academic motivation, and school performance, and with more positive peer relations and prosocial behavior (Ghavami et al., 2011; Rivas-Drake et al., 2014). For teenagers faced with adversity, ethnic identity is a powerful source of resilience.

Forming a **bicultural identity**—by exploring and adopting values from both the adolescent's subculture and the dominant culture—offers added benefits. Biculturally identified adolescents tend to be achieved in other identity domains, to have a more secure ethnic identity, and to have especially positive relations with members of other ethnic groups (Basilio et al., 2014; Phinney, 2007). In sum, achievement of ethnic identity enhances many aspects of emotional and social development.

## Applying what we Know

### Supporting Healthy Identity Development

STRATEGY	EXPLANATION
Engage in warm, open communication.	Provides both emotional support and freedom to explore values and goals.
Initiate discussions that promote high-level thinking at home and at school.	Encourages rational and deliberate selection among beliefs and values.
Provide opportunities to participate in extracurricular activities and vocational training programs.	Permits young people to explore the real world of adult work.
Provide opportunities to talk with adults and peers who have worked through similar identity questions.	Offers models of identity achievement and advice on how to resolve identity concerns.
Refrain from gender stereotyping and exerting pressure to conform to gender roles, instead emphasizing exploration of options based on values, interests, and talents.	Frees young people to form a gender identity based on inner traits rather than societal expectations, thereby fostering gender contentedness and psychological well-being (see page 351 in Chapter 10).
Create safe, affirming school and community environments for sexual minority youths.	Promotes integration of sexual orientation into a broader sense of personal identity (see page 382 in Chapter 11).
Provide opportunities to explore ethnic heritage and learn about other cultures in an atmosphere of respect.	Fosters identity achievement in all areas as well as valuing of ethnic diversity, which supports the identity explorations of others.

## Moral Development

**12.4** Describe Kohlberg's theory of moral development, and evaluate its accuracy.

**12.5** Describe influences on moral reasoning and its relation to moral behavior.

Eleven-year-old Sabrina sat at the kitchen table reading the Sunday newspaper, her eyes wide with interest. “Look at this!” she said to 16-year-old Louis, who was munching cereal. Sabrina held up a page of large photos showing a 70-year-old woman standing in her home. The floor and furniture were piled with stacks of newspapers, cardboard boxes, tin cans, glass containers, food, and clothing. The accompanying article described crumbling plaster on the walls, frozen pipes, and nonfunctioning sinks, toilet, and furnace. The headline read: “Loretta Perry: My Life Is None of Their Business.”

“Look what they’re trying to do to this poor lady,” exclaimed Sabrina. “They’re throwing her out of her house and tearing it down! Those city inspectors must not care about anyone. Here it says, ‘Mrs. Perry has devoted much of her life to doing favors for people.’ Why doesn’t someone help *her*?”

“Sabrina, you’re missing the point,” Louis responded. “She’s violating 30 building code standards. The law says you’re supposed to keep your house clean and in good repair.”

“But Louis, she’s old, and she needs help. She says her life will be over if they destroy her home.”

“The building inspectors aren’t being mean, Sabrina. She’s refusing to obey the law. And she’s not just a threat to herself—she’s a danger to her neighbors, too. Suppose her house caught

on fire. You can’t live around other people and say your life is nobody’s business.”

“You don’t just knock someone’s home down,” Sabrina replied with exasperation. “Why aren’t her friends and neighbors over there fixing up that house? You’re just like those building inspectors, Louis. You’ve got no feelings!”

As Louis and Sabrina’s discussion illustrates, cognitive development and expanding social experiences permit adolescents to better understand larger social structures—societal institutions and law-making systems—that govern moral responsibilities. As their grasp of social arrangements expands, adolescents construct new ideas about what should be done when the needs and desires of people conflict. As a result, they move toward increasingly just, fair, and balanced solutions to moral problems.

### Kohlberg's Theory of Moral Development

Early work by Piaget on the moral judgment of the child inspired Lawrence Kohlberg’s more comprehensive cognitive-developmental theory of moral understanding. Kohlberg used a clinical interviewing procedure in which he presented European-American 10- to 16-year-old boys with hypothetical *moral dilemmas*—stories involving a conflict between two moral values—and asked them what the main actor should do and why. Then he followed the participants longitudinally, reinterviewing them at 3- to 4-year intervals over the next 20 years. The best known of Kohlberg’s dilemmas, the “Heinz dilemma,” pits the value of obeying the law (not stealing) against the value of human life (saving a dying person):

In Europe a woman was near death from cancer. There was one drug the doctors thought might save her. A druggist in the same town had discovered it, but he was charging ten times what the drug cost him to make. The sick woman's husband, Heinz, went to everyone he knew to borrow the money, but he could only get together half of what it cost. The druggist refused to sell the drug for less or let Heinz pay later. So Heinz became desperate and broke into the man's store to steal the drug for his wife. Should Heinz have done that? Why or why not? (paraphrased from Colby et al., 1983, p. 77)

Kohlberg emphasized that it is *the way an individual reasons about the dilemma, not the content of the response* (whether or not to steal), that determines moral maturity. Individuals who believe Heinz should take the drug and those who think he should not can be found at each of Kohlberg's first four stages. Only at the two highest stages do moral reasoning and content come together in a coherent ethical system (Kohlberg, Levine, & Hower, 1983). Given a choice between obeying the law and preserving individual rights, the most advanced moral thinkers support individual rights (in the Heinz dilemma, stealing the drug to save a life). Does this remind you of adolescents' efforts to formulate a sound, well-organized set of personal values in constructing an identity? According to some theorists, the development of identity and moral understanding are part of the same process (Bergman, 2004; Blasi, 1994).

**Kohlberg's Stages of Moral Understanding.** Kohlberg organized moral development into three levels, each with two stages, yielding six stages in all. He believed that moral understanding is promoted by the same factors Piaget thought were important for cognitive development: (1) actively grappling with moral issues and noticing weaknesses in one's current reasoning, and (2) gains in perspective taking, which permit individuals to resolve moral conflicts in more effective ways.

**The Preconventional Level.** At the **preconventional level**, morality is externally controlled. Children accept the rules of authority figures and judge actions by their consequences. Behaviors that result in punishment are viewed as bad, those that lead to rewards as good.

- *Stage 1: The punishment and obedience orientation.* Children find it difficult to consider two points of view in a moral dilemma. As a result, they overlook people's intentions and focus on fear of authority and avoidance of punishment as reasons for behaving morally. To the Heinz dilemma, an individual who opposes stealing the drug might say, "If you steal, you'll either be sent to jail or have to live in fear of the police finding you."
- *Stage 2: The instrumental purpose orientation.* Children become aware that people can have different perspectives in a moral dilemma, but at first this understanding is concrete. They view right action as flowing from self-interest and understand reciprocity as equal exchange of favors: "You do this for me and I'll do that for you." They might argue that Heinz should steal the drug because "then he'll still have his wife to keep him company."

**The Conventional Level.** At the **conventional level**, individuals regard conformity to social rules as important, but not for reasons of self-interest. Rather, they believe that actively maintaining the current social system ensures positive relationships and societal order.

- *Stage 3: The "good boy–good girl" orientation, or the morality of interpersonal cooperation.* The desire to obey rules because they promote social harmony first appears in the context of close personal ties. Stage 3 individuals want to maintain the affection and approval of friends and relatives by being a "good person"—trustworthy, helpful, and nice. The capacity to view a relationship from the vantage point of an impartial, outside observer, which requires recursive thought (see page 312 in Chapter 9), supports this new approach to morality. Individuals now understand *ideal reciprocity*: They express the same concern for the welfare of another as they do for themselves—a standard of fairness summed up by the Golden Rule: "Do unto others as you would have them do unto you." An individual favoring Heinz stealing might explain, "Your family will think you're a decent, caring husband if you do."
- *Stage 4: The social-order-maintaining orientation.* At this stage, the individual takes into account a larger perspective—that of societal laws. Moral choices no longer depend on close ties to others. Instead, rules must be enforced in the same evenhanded fashion for everyone, and each member of society has a personal duty to uphold them. The Stage 4

© STEVE SKJOLD/ALAMY

If this teenager helps a preschooler climb an amusement park rope ladder because she expects a favor from someone in return, she is at Kohlberg's preconventional level. If she is guided by ideal reciprocity—"Do unto others as you would have them do unto you"—she has advanced to the conventional level.

individual believes that laws should never be disobeyed because they are vital for ensuring societal order and cooperation between people. Arguing against Heinz stealing, a person might say, “Heinz has a duty like everyone else to obey the law. If he’s allowed to break the law because of a tough situation, others will think they can, too. We’ll have chaos, not a law-abiding society.”

**The Postconventional or Principled Level.** Individuals at the **postconventional level** move beyond unquestioning support for their own society’s rules and laws. They define morality in terms of abstract principles and values that apply to all situations and societies.

- **Stage 5: The social contract orientation.** At Stage 5, individuals can imagine alternatives to their own social order, and they emphasize fair procedures for interpreting and changing the law. When laws are consistent with individual rights and the interests of the majority, each person follows them because of a *social contract orientation*—free and willing participation in the system because it brings about more good for people than if it did not exist. A person favoring Heinz stealing might explain, “Although there is a law against stealing, it wasn’t meant to violate a person’s right to life. If Heinz is prosecuted, the law needs to be reinterpreted to take into account people’s natural right to keep on living.”
- **Stage 6: The universal ethical principle orientation.** At this highest stage, right action is defined by self-chosen ethical principles of conscience that are valid for all people, regardless of law and social agreement. Stage 6 individuals typically mention such abstract principles as respect for the worth and dignity of each person, as in this response defending Heinz stealing the drug: “It doesn’t make sense to put respect for property above respect for life. People could live together without private property at all. Respect for human life is absolute and accordingly people have a mutual duty to save one another from dying” (paraphrased from Rest, 1979, p. 37).

**Research on Kohlberg’s Stage Sequence.** Kohlberg’s original research and other longitudinal studies confirm that with few exceptions, individuals move through his first four stages in the predicted order (Boom, Wouters, & Keller, 2007; Dawson, 2002; Walker & Taylor, 1991). Moral development is slow and gradual: Reasoning at Stages 1 and 2 decreases in early adolescence, while Stage 3 increases through midadolescence and then declines. Stage 4 reasoning rises over the teenage years until, among college-educated young adults, it is the typical response.

Few people move beyond Stage 4. In fact, postconventional morality is so rare that no clear evidence exists that Kohlberg’s Stage 6 actually follows Stage 5. This poses a key challenge to Kohlberg’s theory: If people must reach Stages 5 and 6 to be considered truly morally mature, few individuals anywhere would measure up! According to one reexamination of Kohlberg’s stages, moral maturity can be found in a revised understanding of Stages 3 and 4 (Gibbs, 2014). These stages are not “conventional”—based on social conformity—as Kohlberg assumed.

Rather, they require profound moral constructions—an understanding of ideal reciprocity as the basis for relationships (Stage 3) and for widely accepted moral standards, set forth in rules and laws (Stage 4). In this view, “postconventional” morality is a highly reflective endeavor limited to a handful of people who have attained advanced education, usually in philosophy.

Think of an actual moral dilemma you faced recently. Real-life conflicts often elicit moral thinking below a person’s actual capacity because they involve practical considerations. Although adolescents and adults mention reasoning as their most frequent strategy for resolving these dilemmas, they also refer to other strategies—talking through issues with others, relying on intuition, and calling on religious and spiritual ideas. And they report feeling drained, confused, and torn by temptation—an emotional side of moral judgment not tapped by hypothetical situations (Walker, 2004). Hypothetical dilemmas evoke the upper limits of moral thought because they allow reflection without the interference of personal risk.

The influence of situational factors on moral judgments indicates that like Piaget’s cognitive stages, Kohlberg’s moral stages are loosely organized and overlapping. Rather than developing in a neat, stepwise fashion, people draw on a range of moral responses that vary with context. With age, this range shifts upward as less mature moral reasoning is gradually replaced by more advanced moral thought.

## Are There Sex Differences in Moral Reasoning?

As we have seen, real-life moral dilemmas often highlight the role of emotion in moral judgment. In the discussion at the beginning of this section, notice how Sabrina’s moral argument focuses on caring and commitment to others. Carol Gilligan (1982) is the best-known of those who have argued that Kohlberg’s theory does not adequately represent the morality of girls and women. Gilligan believes that feminine morality emphasizes an “ethic of care” that Kohlberg’s system devalues. Sabrina’s reasoning falls at Stage 3 because it is based on mutual trust and affection, whereas Louis’s is at Stage 4 because he emphasizes following the law. According to Gilligan, a concern for others is a *different* but no less valid basis for moral judgment than a focus on impersonal rights.

Many studies have tested Gilligan’s claim that Kohlberg’s approach underestimates the moral maturity of females, and most do not support it (Walker, 2006). On hypothetical dilemmas as well as everyday moral problems, adolescent and adult females display reasoning at the same stage as their male agemates, and often at a higher stage. Themes of justice and caring appear in the responses of both sexes and when females do raise interpersonal concerns, they are not downgraded in Kohlberg’s system (Walker, 1995). These findings suggest that although Kohlberg emphasized justice rather than caring as the highest moral ideal, his theory taps both sets of values.

Nevertheless, some evidence indicates that although the morality of males and females taps both orientations, females do tend to emphasize care, whereas males either stress justice or focus equally on justice and care (You, Maeda, & Bebeau, 2011). This

difference in emphasis, which appears more often in real-life than in hypothetical dilemmas, may reflect women's greater involvement in daily activities involving care and concern for others.

Indeed, context profoundly affects use of a care orientation. In one study, researchers presented 18- to 38-year-old university students with one of three versions of a moral dilemma, in which the main character varied in familiarity: (1) a close friend in class, (2) a person "known only vaguely" from class, or (3) a classmate whose relationship was unspecified (Ryan, David, & Reynolds, 2004). When asked whether they would permit the character, who was in danger of failing the course, to borrow a copy of their recently completed assignment despite risk of cheating, both males and females gave more care responses when considering a close friend than a socially distant classmate. Gender differences emerged only in the unspecified condition, where females—who tend to forge closer relationships and, thus, may have assumed greater familiarity—expressed more caring.

## Coordinating Moral, Social-Conventional, and Personal Concerns

Adolescents' moral advances are also evident in their reasoning about situations that raise competing moral, social-conventional, and personal issues. In diverse Western and non-Western cultures, concern with matters of personal choice strengthens during the teenage years—a reflection of adolescents' quest for identity and increasing independence (Rote & Smetana, 2015). As young people firmly insist that parents not encroach on the personal arena (dress, hairstyle, diary records, friendships), disputes over these issues increase. Teenagers whose parents frequently intrude into their personal affairs report greater psychological stress. In contrast, adolescents typically say that parents have a right to tell them what to do in moral and social-conventional situations (Helwig, Ruck, & Peterson-Badali, 2014). And when these issues spark disagreements, teenagers seldom challenge parental authority.

As they enlarge the range of issues they regard as personal, adolescents think more intently about conflicts between personal choice and community obligation—for example, whether, and under what conditions, it is permissible to restrict speech, religion, marriage, group membership, and other individual rights. When asked if it is OK to exclude a child from a peer group on the basis of race or gender, fourth graders usually say exclusion is always unfair. But by tenth grade, young people, though increasingly mindful of fairness, indicate that under certain conditions—in intimate relationships (friendship) and private contexts (at home or in a small club), and on the basis of gender more often than race—exclusion is OK (Killen et al., 2002, 2007; Rutland, Killen, & Abrams, 2010). In explaining, they mention the right to personal choice as well as concerns about effective group functioning.

As adolescents integrate personal rights with ideal reciprocity, they demand that the protections they want for themselves extend to others. For example, older high school students are more likely than their younger counterparts to believe that gay and lesbian youths have the right to be free of discrimination in school, and they justify with moral reasoning: "We should treat others as we wish to be treated ourselves" (Horn & Heinze,

© MARLYN HUMPHRIES/THE IMAGE WORKS

Boston teenagers protest against rising public transportation fares and in favor of a discounted youth pass. Adolescent moral development involves demanding that the protections one wants for oneself extend to others.

2011). And with age, teenagers increasingly defend the government's right to limit individual freedom to engage in risky health behaviors, such as smoking and drinking, in the interest of the larger public good (Flanagan, Stout, & Galloway, 2008).

Similarly, adolescents are increasingly mindful of the overlap between moral imperatives and social conventions. Eventually they realize that violating strongly held conventions—showing up at a wedding in a T-shirt, talking out of turn at a student council meeting—can harm others, either by inducing distress or by undermining fair treatment. As their grasp of fairness deepens, young people understand that many social conventions have moral implications: They are vital for maintaining a just and peaceful society (Nucci, 2001). Notice how this understanding is central to Kohlberg's Stage 4, which is typically attained as adolescence draws to a close.

## Influences on Moral Reasoning

Many factors affect maturity of moral reasoning, including child-rearing practices, peer interaction, schooling, and culture. Growing evidence suggests that, as Kohlberg believed, these experiences work by presenting young people with cognitive challenges, which stimulate them to think about moral problems in more complex ways.

**Parenting Practices.** Adolescents who gain most in moral understanding have parents who engage in moral discussions, encourage prosocial behavior, insist that others be treated respectfully and fairly, and create a supportive atmosphere by listening sensitively, asking clarifying questions, and presenting higher-level reasoning (Carlo, 2014; Pratt, Skoe, & Arnold, 2004). In one study, 11-year-olds were asked what they thought an adult would say to justify a moral rule, such as not lying, stealing, or breaking a promise. Those with warm, demanding, communicative parents were far more likely than their agetates to point to the importance of ideal reciprocity: "You wouldn't like it if I did it to you" (Leman, 2005).

**Peer Interaction.** Interaction among peers who present differing viewpoints promotes moral understanding. When young people negotiate and compromise, they realize that social life can be based on cooperation between equals. Adolescents who report more close friendships and who more often participate in conversations with their friends are advanced in moral reasoning (Schonert-Reichl, 1999). The mutuality and intimacy of friendship, which foster decisions based on consensual agreement, may be particularly important for enhancing adolescents' understanding of fairness and justice.

Furthermore, recall from Chapter 10 that intergroup contact—cross-race friendships and interactions in schools and communities—reduces racial and ethnic prejudice. It also affects young people morally, strengthening their conviction that race-based, sexual orientation-based, and other forms of peer exclusion are wrong (Horn & Sinno, 2014; Ruck et al., 2011).

Peer discussions and role-playing of moral problems have provided the basis for interventions aimed at improving high school and college students' moral understanding. For these discussions to be effective, young people must be highly engaged—confronting, critiquing, and attempting to clarify one another's viewpoints, as Sabrina and Louis did when they argued over Mrs. Perry's plight (Berkowitz & Gibbs, 1983; Comunian & Gielen, 2006). And because gains in maturity of moral reasoning occur gradually, many peer interaction sessions over weeks or months typically are needed to produce moral change.

**Schooling.** Secondary schools with nondiscrimination and antibullying policies and student organizations that support the rights of minorities (such as gay–straight alliances) enhance adolescents' moral reasoning about discrimination. In one study, students attending a high school with these practices in place were more likely than those in a school without such practices to view exclusion and harassment of gay and lesbian peers as unjust (Horn & Szalacha, 2009). Teachers who create classroom climates of fairness and respect are similarly influential. Tenth graders who reported fair teacher treatment were more likely than those who had experienced unjust treatment (an undeserved detention or low grade) to view excluding a peer on the basis of race as a moral transgression (Crystal, Killen, & Ruck, 2010). When schools convey explicit messages about the harm inflicted by prejudice and harassment, they induce students to think about those behaviors in ethical terms.

Furthermore, moral reasoning typically progresses to Kohlberg's higher stages the longer a person remains in school (Gibbs et al., 2007). College environments are especially influential because they introduce young people to social issues that extend beyond personal relationships to entire political and cultural groups. In line with this idea, college students who report more perspective-taking opportunities—classes that emphasize open discussion of opinions and friendships with others of different cultural backgrounds—and who indicate that they have become more aware of social diversity tend to be advanced in moral reasoning (Comunian & Gielen, 2006; Mason & Gibbs, 1993a, 1993b).

**Culture.** Individuals in industrialized nations move through Kohlberg's stages more quickly and progress to higher stages

KYODO/AP IMAGES

In Japan, a country that highly values interdependence, responses to moral dilemmas tend to emphasize caring as a communal responsibility. These high school students express their student body's collective empathy during a memorial visit to a school devastated by the 2011 tsunami.

than do individuals in village societies, who rarely move beyond Stage 3. One explanation for these cultural differences is that in village societies, moral cooperation is based on direct relations between people and does not allow for the development of advanced moral understanding (Stages 4 to 6), which depends on appreciating the role of larger social structures, such as laws and government institutions (Gibbs et al., 2007).

A second possible reason for cultural variation is that in both village societies and industrialized cultures that highly value interdependence, responses to moral dilemmas are more other-directed than in North America and Western Europe (Miller & Bland, 2014). In one study, both male and female Japanese adolescents, who almost always integrated care- and justice-based reasoning, placed greater weight on caring, which they regarded as a communal responsibility (Shimizu, 2001). Similarly, in research conducted in India, even highly educated people (expected to have attained Kohlberg's Stages 4 and 5) viewed solutions to moral dilemmas as the responsibility of the entire society, not of a single person (Miller & Bersoff, 1995).

These findings raise the question of whether Kohlberg's highest level represents a culturally specific way of thinking—one limited to Western societies that emphasize individualism and an appeal to an inner, private conscience. At the same time, a review of over 100 studies confirmed an age-related trend consistent with Kohlberg's Stages 1 to 4 across diverse societies (Gibbs et al., 2007). A common morality of justice is clearly evident in the dilemma responses of people from vastly different cultures.

## Moral Reasoning and Behavior

A central assumption of the cognitive-developmental perspective is that moral understanding should affect moral action. According to Kohlberg, mature moral thinkers realize that behaving in line with their beliefs is vital for creating and maintaining a just social world (Gibbs, 2014). Consistent with this idea, higher-stage adolescents more often act prosocially by helping, sharing,

and defending victims of injustice and by volunteering in their communities (Carlo et al., 2011; Comunian & Gielen, 2000, 2006). Also, they less often engage in cheating, aggression, and other antisocial behaviors (Raaijmakers, Engels, & van Hoof, 2005; Stams et al., 2006).

Yet the connection between more mature moral reasoning and action is only modest. As we have seen, moral behavior is influenced by many factors besides cognition, including the emotions of empathy, sympathy, and guilt; individual differences in temperament; and cultural experiences and intuitive beliefs that affect moral decision making. Compared with children, adolescents increasingly say they would feel negatively after committing a moral transgression and positively after acting morally (Krettenauer et al., 2014). Moral decisions and anticipated emotions become better coordinated over time, contributing to gains in teenagers' motivation to act morally.

**Moral identity**—the degree to which morality is central to self-concept—also affects moral behavior (Hardy & Carlo, 2011). In a study of low-SES African-American and Hispanic teenagers, those who emphasized moral traits and goals in their self-descriptions displayed exceptional levels of community service (Hart & Fegley, 1995). And when 10- to 18-year-olds rated moral traits on the basis of whether each reflected the kind of person they wanted to be, those with a stronger *moral ideal self* were viewed by their parents as more ethical and altruistic in behavior (Hardy et al., 2012).

Researchers are identifying factors that strengthen moral identity in hopes of capitalizing on them to promote moral commitment. Certain parenting practices—inductive discipline (see page 267 in Chapter 8) and clearly conveyed moral expectations—augment adolescents' moral identity (Patrick & Gibbs, 2011). Also, opportunities to enact moral behaviors through community service enhance adolescents' self-understanding, thereby contributing to a stronger moral identity and, in turn, to moral motivation (Matsuba, Murzyn, & Hart, 2014). As the Social Issues: Education box on the following page reveals, civic engagement can help young people see the connection between their personal interests and the public interest—an insight that may foster all aspects of morality.

## Religious Involvement and Moral Development

Recall that in resolving real-life moral dilemmas, many people express religious and spiritual ideas. Though the percentage of religiously unaffiliated U.S. adults rose over the past decade, about 70 percent of Americans continue to rate religion as very important in their lives. Comparable figures are 50 percent in Canada and Germany, 40 percent in Great Britain, and 30 percent in Sweden, making the United States the most religious Western nation (Pew Research Center, 2012, 2015a; Pickel, 2013). People who regularly attend religious services include many parents with children. But as adolescents search for a personally meaningful identity, formal religious involvement declines—for U.S. youths, from 55 percent at ages 13 to 15 to 36 percent at age 18 (Pew Research Center, 2010c, 2015a).

© MARWAJUKET, JOHN/ALAMY

Singing in a church choir gives these youths a sense of connection to their faith and to adults and peers who hold similar values. Adolescents who participate in a religious community are more likely to engage in community service activities and to display responsible academic and social behavior.

Nevertheless, teenagers who remain part of a religious community are advantaged in moral values and behavior. Compared with nonaffiliated youths, they are more involved in community service activities aimed at helping the less fortunate (Kerestes, Youniss, & Metz, 2004). And religious involvement promotes responsible academic and social behavior and discourages misconduct (Dowling et al., 2004). It is associated with lower levels of drug and alcohol use, early sexual activity, and antisocial behavior (Good & Willoughby, 2014; Salas-Wright, Vaughn, & Maynard, 2014).

A variety of factors contribute to these favorable outcomes. In a study of inner-city high school students, religiously involved young people were more likely to report trusting relationships with parents, other adults, and friends who hold similar worldviews. The more activities they shared with this network, the higher they scored in empathy and prosocial behavior (King & Furrow, 2004). Furthermore, religious education and youth activities directly teach concern for others and provide opportunities for moral discussions and civic engagement. And adolescents who feel connected to a higher being may develop certain inner strengths, including sense of self-efficacy, prosocial values, and a strong moral identity, that help them translate their thinking into action (Hardy & Carlo, 2005; Sherrod & Spiewak, 2008).

At the same time, religious or political messages that convey stereotypes and prejudices about minorities work against youths' moral maturity. In focus groups addressing the impact of religion in their lives, Muslim adolescents from U.S. immigrant families, while recognizing the support their religious communities provided, frequently mentioned negative experiences of profiling and other forms of discrimination at the hands of non-Muslims (Abo-Zena & Barry, 2013).

Finally, religious cults that target alienated youths as potential members, rigidly indoctrinating them into the group's beliefs, estranging them from former social ties, and suppressing individuality, interfere with virtually all developmental tasks of adolescence, including moral progress (Scarlett & Warren, 2010). Although religious communities may be uniquely suited to foster teenagers' moral and prosocial commitments, not all have these effects.

## Social Issues: Education

### Development of Civic Engagement

On Thanksgiving Day, Jules, Martin, Louis, and Sabrina joined their parents to serve a holiday dinner to poverty-stricken people. Throughout the year, Sabrina volunteered on Saturday mornings at a nursing home. During a congressional election campaign, all four adolescents raised questions about issues at special youth meetings with candidates. At school, Louis and his girlfriend, Cassie, formed an organization devoted to promoting ethnic and racial tolerance.

These young people show a strong sense of *civic engagement*—a complex combination of cognition, emotion, and behavior. Civic engagement involves knowledge of social and political issues, commitment to making a difference in the community, and skills for achieving civic goals, such as how to resolve differing views fairly (Zaff et al., 2010).

When young people engage in community service that exposes them to people in need or to public issues, they are especially likely to express a commitment to future service. And youth volunteers—who tend to be advanced in moral reasoning—gain further in moral maturity as a result of participating (Gibbs et al., 2007; Hart, Atkins, & Donnelly, 2006). Family, school, and community experiences contribute to adolescents' civic engagement.

#### Family Influences

Adolescents whose parents stress compassion for the less fortunate and engage in community service tend to hold socially responsible values. When asked what causes unemployment or poverty, these teenagers more often mention situational and societal factors (lack of education, government policies, or the state of the economy) than individual factors (low intelligence or personal problems). Youths who endorse situational and societal causes, in turn, have more altruistic life goals, such as working to eradicate poverty or to preserve the earth for future generations (Flanagan & Tucker, 1999).

Parents' open communication, discussion of social problems, and own civic engagement

carry over to their adolescent children's civic commitment and behavior (van Goethem et al., 2014). These young people not only volunteer but do so especially often.

#### School and Community Influences

A democratic climate at school, in which teachers promote respectful discussion of controversial issues, fosters knowledge and critical analysis of social and political concerns and participation in organizations with a civic purpose (Lenzi et al., 2012; Torney-Purta, Barber, & Wilkenfeld, 2007). Furthermore, high school students who view their community as one in which adults care about youths and work to make the community better report higher levels of civic participation (Kahne & Sporte, 2008). Participation in extracurricular activities at school whose primary objectives are to induce social change outside the organization itself is also associated with civic commitment that persists into adulthood (Obradović & Masten, 2007).

Two aspects of these involvements seem to account for their lasting impact. First, they introduce adolescents to the vision and skills required for mature civic engagement. Within student government, political and vocational clubs, service organizations, and student newspaper and yearbook staffs, young people see how their actions affect the wider school and community. They realize that collectively they can achieve results greater than any one person can accomplish alone. And they learn to work together, balancing strong convictions with compromise (Kirshner, 2009). Second, while engaged in these activities, young people explore political and moral ideals. Often they redefine their identities to include a

A high school student plays music for a hospice patient as part of a service project he started. Youths who volunteer in their communities gain in moral maturity and are especially likely to engage in future service.

responsibility to combat others' misfortunes, which further strengthens civic engagement (Crocetti, Jahromi, & Meeus, 2012).

The majority of U.S. public schools provide students with community service opportunities. Many schools have *service-learning programs*, which integrate service activities into the academic curriculum. High school students who are required to serve their communities express as strong a desire to remain engaged as do students who volunteer. And when they reach early adulthood, they are equally likely to vote and participate in community organizations (Hart et al., 2007).

Still, most U.S. schools offering service learning do not have policies encouraging or mandating enrollment in such programs. Furthermore, low-SES, inner-city youths attend schools and live in neighborhoods with fewer civic-training opportunities. And students without plans to go to college may be less motivated to enroll in service-learning programs. As a result, these youths score substantially lower than higher-SES and college-oriented youths in civic knowledge and participation (Lenzi et al., 2012; Syvertsen et al., 2011). A broad societal commitment to fostering civic character must pay special attention to supportive school and community experiences for these young people.

## Further Challenges to Kohlberg's Theory

Although much evidence is consistent with the cognitive-developmental approach to morality, Kohlberg's theory has faced major challenges. The most radical opposition comes from researchers who—referring to wide variability in moral reasoning across situations—claim that Kohlberg's stage sequence inadequately accounts for morality in everyday life. These investigators favor abandoning Kohlberg's stages for a *pragmatic approach to morality* (Krebs, 2011). They assert that each person makes moral judgments at varying levels of maturity, depending on the individual's current context and motivations: Conflict over a business deal is likely to evoke Stage 2 (instrumental purpose) reasoning, a friendship or romantic dispute Stage 3 (ideal reciprocity) reasoning, and a breach of contract Stage 4 (social-order-maintaining) reasoning.

According to the pragmatic view, everyday moral judgments—rather than being efforts to arrive at just solutions—are practical tools that people use to achieve their goals. To benefit personally, they often must advocate cooperation with others. But people often act first and then invoke moral judgments to rationalize their actions, regardless of whether their behavior is self-centered or prosocial (Haidt, 2013). And sometimes people use moral judgments for immoral purposes—for example, to excuse their transgressions.

Is the pragmatic approach correct that people strive to resolve moral conflicts fairly only when they themselves have nothing to lose? Supporters of the cognitive-developmental perspective point out that people frequently rise above self-interest to defend others' rights. Also, adolescents and adults are well aware of the greater adequacy of higher-stage moral reasoning, which some people act on despite highly corrupt environments. And individuals who engage in sudden altruistic action may have previously considered relevant moral issues so thoroughly that their moral judgment activates automatically, triggering an immediate response (Gibbs, 2014; Gibbs et al., 2009). In these instances, people who appear to be engaging in after-the-fact moral justification are actually behaving with great forethought.

In sum, the cognitive-developmental approach to morality has done much to clarify our profound moral potential. And despite opposition, Kohlberg's central assumption—that with age, humans everywhere construct a deeper understanding of fairness and justice that guides moral action—remains powerfully influential.

### Ask yourself

**CONNECT** What advance in perspective taking contributes to an understanding of ideal reciprocity, and why is that understanding vital for mature moral reasoning?

**APPLY** Tam grew up in a small village culture, Lydia in a Western industrial city. At age 15, Tam reasons at Kohlberg's Stage 3, Lydia at Stage 4. What factors might account for the difference?

**REFLECT** Do you favor a cognitive-developmental or a pragmatic approach to morality, or both? Explain, drawing on research evidence and personal experiences.

## The Family

**12.6** Discuss changes in parent–child and sibling relationships during adolescence.

Franca and Antonio remember their son Louis's freshman year of high school as a difficult time. Because of a demanding project at work, Franca was away from home many evenings and weekends. In her absence, Antonio took over, but when business declined and he had to cut costs at his hardware store, he, too, had less time for the family. That year, Louis and two friends used their computer know-how to gain entry to their classmates' systems to pirate video game software. Louis's grades fell, and he often left the house without saying where he was going. Franca and Antonio began to feel uncomfortable about the long hours Louis spent at his computer and their lack of contact with him. One day, when Franca and Antonio noticed the video game icons covering Louis's computer desktop, they knew they had cause for concern.

Development at adolescence involves striving for **autonomy**—a sense of oneself as a separate, self-governing individual. Adolescent autonomy has two vital aspects: (1) an *emotional component*—relying more on oneself and less on parents for support and guidance, and (2) a *behavioral component*—making decisions independently by carefully weighing one's own judgment and the suggestions of others to arrive at a personally satisfying, well-reasoned course of action (Collins & Laursen, 2004). Nevertheless, relationships with parents remain vital for helping adolescents become autonomous, responsible individuals.

## Parent–Adolescent Relationships

A variety of changes within the adolescent support autonomy. In Chapter 11, we saw that puberty triggers psychological distancing from parents. In addition, as young people look more mature, parents give them more freedom to think and decide for themselves, more opportunities to regulate their own activities, and more responsibility (McElhaney et al., 2009). Cognitive development also contributes: Gradually, adolescents make decisions more effectively, and an improved ability to reason about social relationships leads teenagers to *deidealize* their parents, viewing them as “just people.” Consequently, they no longer bend as easily to parental authority. Yet as Franca and Antonio's episode with Louis reveals, teenagers still need guidance and protection from dangerous situations.

**Effective Parenting.** Think back to the type of parenting that fosters academic achievement (Chapter 11), identity formation, and moral maturity. You will find a common theme: Effective parenting of adolescents strikes a balance between *connection* and *separation*. Autonomy is fostered by warm, supportive parent–adolescent ties that make appropriate demands for maturity while permitting young people to explore ideas and social roles—across diverse ethnic and SES groups, nationalities, and family structures (including single-parent, two-parent,

and stepparent). Autonomy, in turn, predicts high self-reliance, self-regulation, academic achievement, positive work orientation, favorable self-esteem, and ease of separation in the transition to college (Bean, Barber, & Crane, 2007; Eisenberg et al., 2005; Supple et al., 2009; Vazsonyi, Hibbert, & Snider, 2003; Wang, Pomerantz, & Chen, 2007).

Conversely, parents who are coercive or psychologically controlling interfere with the development of autonomy. These tactics are linked to low self-esteem, depression, drug and alcohol use, and antisocial behavior—outcomes that often persist into early adulthood (Allen et al., 2012; Barber, Stolz, & Olsen, 2005; Lansford et al., 2014).

In Chapter 2, we described the family as a *system* that must adapt to changes in its members. The rapid physical and psychological changes of adolescence trigger conflicting expectations in parent–child relationships. Earlier we noted that interest in making choices about personal matters strengthens in adolescence. Yet parents and teenagers—especially young teenagers—differ sharply on the appropriate age for granting certain privileges, such as control over clothing, school courses, going out with friends, and dating (Smetana, 2002). Consistent parental monitoring of the young person’s daily activities, through a cooperative relationship in which the adolescent willingly discloses information, is linked to a variety of favorable outcomes—prevention of delinquency, reduction in sexual activity, improved school performance, and positive psychological well-being (Crouter & Head, 2002; Lippold et al., 2014).

### LOOK and LISTEN

Ask an early adolescent and his or her parent for their views on when the young person is mature enough to begin dating, create a Facebook page, and be given other privileges. Do adolescent and parent perspectives differ?

© ELLEN B. SENISI

Effective parenting, which balances connection and separation, promotes autonomy in adolescence. Teenagers benefit from freedom to explore ideas and make their own decisions, but they still need guidance and protection from dangerous situations.

© LAURA DWIGHT PHOTOGRAPHY

Chinese adolescents tend to readily accept their parents’ decisions because they value parents’ opinions, not because they feel pressured to comply.

**Culture.** In cultures that place a high priority on interdependence, autonomy remains a central adolescent motive, but teenagers conceive of it differently than in Western nations. Rather than equating it with independent decision making, they view autonomy as *self-endorsed* decision making—engaging in actions that are consistent with authentic personal values. In an investigation of adolescents from both urban and rural regions of China, self-endorsed motives for both independent and “dependent” decision making (following parents’ advice) were related to high self-esteem and a positive outlook (Chen et al., 2013). Chinese adolescents often accept their parents’ decisions because they value parents’ opinions, not because they feel pressured to comply.

Immigrant parents from cultures that emphasize obedience to authority have greater difficulty adapting to their teenagers’ push for independent decision making, often reacting strongly to adolescent disagreement. And as adolescents acquire the Western host culture’s language and are increasingly exposed to its individualistic values, immigrant parents may become even more critical, prompting teenagers to rely less on the family network for social support and to disclose less about personal feelings, peer relationships, and potentially risky activities (Yau, Tasopoulos-Chan, & Smetana, 2009). The resulting *acculturative stress* is associated with a decline in self-esteem and a rise in anxiety, depressive symptoms, and deviant behavior, including alcohol use and delinquency (Park, 2009; Suarez-Morales & Lopez, 2009; Warner et al., 2006).

But most adolescents from immigrant families attain sufficient psychological separation from their parents to enable healthy psychological development (Fuligni & Tsai, 2015). At the same time, they sustain the strong sense of family obligation instilled by their home culture, flexibly balancing those commitments with the pursuit of autonomy valued in their new society.

**A Reorganized Relationship.** Throughout adolescence, the quality of the parent–child relationship is the single most consistent predictor of mental health (Collins & Steinberg, 2006). The mild to moderate conflict that typically arises facilitates adolescent identity and autonomy by helping family members learn

to express and tolerate disagreement. Conflicts also inform parents of teenagers' changing needs and expectations, signaling a need for adjustments in the parent–child relationship.

By mid- to late adolescence, harmonious interaction is on the rise. The reduced time that Western teenagers spend engaged in activities with their parents—an estimated one-third less than in middle childhood for U.S. adolescents—has little to do with conflict. Rather, it results from the large amount of unstructured time available to Western teenagers—on average, nearly half their waking hours (Larson, 2001; Milkie, Nomaguchi, & Denny, 2015). Young people tend to fill these free hours with activities that take them away from home—part-time jobs, leisure and volunteer pursuits, and time with friends.

Type of shared parent–adolescent activities is more important than quantity of time together. In an investigation of middle-SES white families, engaging in leisure pursuits and eating meals together (especially with both parents) enhanced teenagers' well-being (Offer, 2013). These contexts probably afford parents and adolescents greater opportunity to discuss important concerns in a relaxed atmosphere and to emphasize shared values.

Finally, the drop in family time over the teenage years is not universal. In one study, urban low- and middle-SES African-American youths showed no decline in hours spent with family—a pattern typical in cultures stressing interdependence and family closeness (Larson et al., 2001). Furthermore, teenagers living in risky neighborhoods tend to have more trusting relationships with parents and adjust more favorably when parents maintain tighter control and pressure them not to engage in worrisome behaviors (McElhaney & Allen, 2001). In harsh surroundings, adolescents seem to interpret more measured granting of autonomy as a sign of parental caring.

## Family Circumstances

As Franca and Antonio's experience with Louis reminds us, adult life stress can interfere with warm, involved parenting and, in turn, with children's adjustment during any period of development. But parents who are financially secure, not overloaded with job pressures, and content with their marriages usually find it easier to grant teenagers appropriate autonomy and experience less conflict with them (Cowan & Cowan, 2002). When Franca and Antonio's work stress eased and they recognized Louis's need for more involvement and guidance, his problems subsided.

Among the minority of families with seriously troubled parent–adolescent relationships, most difficulties began in childhood (Collins & Laursen, 2004). Think back to family conditions considered in earlier chapters that pose challenges for adolescents—for example, economic hardship, divorce, single parenthood, blended families, and child maltreatment. Teenagers who develop well despite family stressors continue to benefit from factors that fostered resilience in earlier years: an appealing, easy-going disposition; a parent who combines warmth with high expectations; and (especially if parental supports are lacking) bonds with prosocial adults outside the family who care deeply about the adolescent's well-being (Luthar, Crossman, & Small, 2015).

## Siblings

Like parent–child relationships, sibling interactions adapt to development at adolescence. As younger siblings become more self-sufficient, they accept less direction from their older brothers and sisters. Also, as teenagers become more involved in friendships and romantic relationships, they invest less time and energy in siblings, who are part of the family from which they are trying to establish autonomy. As a result, sibling relationships often become less intense, in both positive and negative feelings (Kim et al., 2006; Whiteman, Solmeyer, & McHale, 2015).

Nevertheless, attachment between siblings remains strong for most young people. Overall, siblings who established a positive bond in early childhood continue to display greater affection and caring, which contribute to more favorable adolescent adjustment, including increased academic engagement, empathy, and prosocial behavior (Lam, Solmeyer, & McHale, 2012; McHale, Updegraff, & Whiteman, 2012). In contrast, sibling negativity—frequent conflict, coercive exchanges, and aggression—is associated with internalizing symptoms (anxiety and depression) and externalizing difficulties (conduct problems, bullying, and drug use) (Criss & Shaw, 2005; Solmeyer, McHale, & Crouter, 2014).

Finally, culture influences the quality of adolescent sibling ties. For example, the Hispanic cultural ideal of *familism*, which highly values close family bonds, fosters harmonious sibling relationships. In one study, Mexican-American adolescents who expressed a strong Mexican cultural orientation resolved sibling conflicts more cooperatively than did those more oriented toward U.S. individualistic values (Killoren, Thayer, & Updegraff, 2008).

## Peer Relations

**12.7** Describe adolescent friendships, peer groups, and dating relationships and their consequences for development.

As adolescents spend less time with family members, peers become increasingly important. In industrialized nations, young people spend most of each weekday with agemates in school as well as much out-of-class time together. In the following sections, we will see that at their best, peers serve as critical bridges between the family and adult social roles. But as with parent and sibling relationships, peer associations vary in quality and in their consequences for teenagers' well-being and adjustment.

## Friendships

Number of best friends declines from about four to six in early adolescence to one or two in adulthood (Gomez et al., 2011). At the same time, the nature of the relationship changes.

**Characteristics of Adolescent Friendships.** When asked about the meaning of friendship, teenagers stress three characteristics. The most important is *intimacy*, or psychological closeness, which is supported by *mutual understanding* of each other's

values, beliefs, and feelings. In addition, more than younger children, teenagers want their friends to be *loyal*—to stick up for them and not leave them for somebody else (Collins & Madsen, 2006).

Teenagers' strong desire for friendship closeness likely explains why they say friends are their most important sources of social support (Brown & Larson, 2009). As frankness and faithfulness increase, *self-disclosure* (sharing of private thoughts and feelings) between friends rises over the adolescent years. As a result, teenage friends get to know each other better as personalities. In addition to the many characteristics that school-age friends share (see page 346 in Chapter 10), adolescent friends tend to be alike in identity status, educational aspirations, political beliefs, depressive symptoms, and willingness to try drugs and engage in lawbreaking acts. Over time, they become increasingly similar in these ways, and the more similar they are, the greater the chances that their friendships will be long-lasting (Bagwell & Schmidt, 2011; Hartl, Laursen, & Cillessen, 2015). Occasionally, however, teenagers choose friends with differing attitudes and values, which permits them to explore new perspectives within the security of a compatible relationship.

During adolescence, cooperation and mutual affirmation between friends increase and negative interaction declines—changes that reflect greater skill at preserving the relationship and sensitivity to a friend's needs and desires (De Goede, Branje, & Meeus, 2009). Adolescents also are less possessive of their friends than they were in childhood (Parker et al., 2005). Desiring a certain degree of autonomy for themselves, they recognize that friends need this, too.

**Gender Differences in Friendship Quality.** Ask several adolescents to describe their close friendships. You are likely to find that emotional closeness is more common between girls than boys (Hall, 2011). Girls frequently get together to “just talk,” and their interactions contain more self-disclosure and mutually supportive statements. In contrast, boys more often gather for an activity—usually sports and competitive games. Boys' discussions usually focus on successes in sports and school and involve more competition and conflict (Brendgen et al., 2001; Rubin, Bukowski, & Parker, 2006).

Because of gender-role expectations, girls' friendships typically focus on communal concerns, boys' on achievement and status. Boys do form close friendship ties, but the quality of their friendships is more variable. When ethnically diverse boys from low-income families were asked to describe their friendships, African Americans, Asian Americans, and Hispanics mentioned closeness, mutual support, and self-disclosure more often than their white counterparts. But as ethnic minority boys transitioned from mid- to late adolescence, many reported a decline in friendship closeness (Way, 2013). Their remarks revealed that masculine stereotypes—to be tough and unemotional—interfered with these bonds. But perhaps because of cultural valuing of emotional expressiveness between male friends, Hispanic boys were more likely than others to resist conforming to gender stereotypes (Way et al., 2014). Such resistance, by permitting boys to benefit from the supportiveness of intimate friends, is consistently related to better adjustment.

© PETER HVIZDAK/THE IMAGE WORKS

Whereas girls tend to emphasize emotional closeness in their friendships, boys more often gather for an activity, such as sports or competitive games. This camper holds up a reward for catching the largest fish, presented to him by his friends.

Friendship closeness, however, can have costs. When friends focus on deeper thoughts and feelings, they tend to *coruminate*, or repeatedly mull over problems and negative emotions, with girls doing so more than boys. Corumination, while contributing to high friendship quality, also triggers anxiety and depression—symptoms more common in girls (Hankin, Stone, & Wright, 2010; Rose et al., 2014). And when conflict arises between intimate friends, more potential exists for one party to harm the other through relational aggression—for example, by divulging sensitive personal information to outsiders. Partly for these reasons, girls' closest same-sex friendships tend to be of shorter duration than boys' (Benenson & Christakos, 2003).

**Friendships, Cell Phones, and the Internet.** Teenagers frequently use cell phones and the Internet to communicate with friends. About 73 percent of U.S. 13- to 17-year-olds own or have access to a smartphone, an additional 15 percent to a basic phone; 58 percent own or have access to a tablet. Although smartphone and tablet ownership is higher among teenagers from economically advantaged families, use of these mobile devices is widespread. They serve as adolescents' primary route to the Internet: 94 percent say they go online daily or more often (Lenhart & Page, 2015).

Texting has become the preferred means of electronic interaction between teenage friends: Most adolescents engage in it, sending and receiving, on average, 30 texts per day. Cell calling ranks second, followed by instant messaging and social media sites: Facebook is favored, but the majority of teenagers also use other platforms. Though used less frequently, e-mailing, video chatting, and online gaming are additional ways teenagers spend time online with friends (see Figure 12.1). Girls text and call their friends more often than boys, and they more often use social media sites to share information (Lenhart et al., 2015). Boys are more avid gamers with friends and other peers.

**FIGURE 12.1** Percentage of U.S. 13- to 17-year-olds using various communication channels to spend time with friends. A sample of more than 1,000 adolescents responded to a survey about their communication strategies with friends. Cell-phone texting was the preferred means of electronic communication, with over half reporting that they used it daily. (Based on Lenhart & Page, 2015.)

Online interaction can contribute to friendship closeness. For example, in several studies, as amount of online messaging between preexisting friends increased, so did young people's perceptions of intimacy in the relationship and sense of well-being (Reich, Subrahmanyam, & Espinoza, 2012; Valkenburg & Peter, 2009). The effect is probably due to friends' online disclosure of personal information, such as worries, secrets, and romantic feelings. But sharing an online activity can also enhance friendship. Most teenage gamers say that playing online games with pre-existing friends makes them feel more connected to those friends (Lenhart et al., 2015). While playing, they often voice-chat or video-chat to converse and collaborate.

Social media sites such as Facebook and Twitter are a major avenue through which teenagers meet new friends: Over one-third of U.S. adolescents report developing friendships this way, often connecting through friends they already know (Lenhart et al., 2015). Girls are especially likely to form new friendships through social media sites; boys more often do so during online gaming.

The quality of adolescents' face-to-face relationships tends to be reproduced in social media communication. In a study of U.S. middle school students diverse in ethnicity and SES, those with positive face-to-face peer relationships had larger networks of social media friends who frequently posted supportive comments (Mikami et al., 2010). Teenagers who reported engaging in delinquent acts tended to post hostile comments to their "About Me" section. And those with depressive symptoms more often uploaded photos of themselves engaging in inappropriate behaviors.

While online communication can augment friendships, clearly it poses risks, which teenage social media users readily verbalize. In a focus group addressing communication technol-

ogy, one high school student reflected, "You don't know how to interact with people anymore because you're always texting." Others said that social media sites too often become contexts for sexually uninhibited posts and for expressed jealousies between friends over dating partners (Rueda, Lindsay, & Williams, 2015). And some mentioned that dialogues through texts and social media sites, which are abbreviated and devoid of nonverbal cues to their sincerity, contribute to misunderstandings and conflicts.

Although 60 percent of U.S. adolescent Facebook users keep their profiles private and 70 percent are friends with their parents, most are relatively unconcerned that information they share might be accessed by third parties without their knowledge. Over half post their e-mail address and one-fifth their cell-phone number. And one-fifth have shared their social media passwords with friends. About 17 percent report contact from strangers that made them feel scared or uncomfortable (Lenhart et al., 2015; Madden et al., 2013).

Finally, adolescent time devoted to social media is rising. For example, nearly one-fourth of U.S. teenagers report using the Internet almost constantly, with 30 percent sending more than 100 texts per day and half of these exceeding 200. On average, adolescent users are on social media sites for nearly 40 minutes per day. Very high social media use is linked to unsatisfying face-to-face social experiences, boredom, and depression (Madden et al., 2013; Pea et al., 2012; Smahel, Brown, & Blinka, 2012). In a longitudinal study, compulsive Internet users (who find it difficult to stop using the Internet and feel frustrated when they don't have access) experienced a rise in mental health problems from grades 8 to 11, irrespective of their preexisting mental health status. Compared to boys, girls were more addicted to social media and reported more impaired mental health (Ciarrochi et al., 2016). These findings suggest that excessive Internet use, especially social media, amplifies adjustment difficulties.

In sum, the Internet's value for enabling convenient and satisfying interaction among teenage friends must be weighed against its potential for facilitating harmful emotional and social consequences. Parents are wise to point out the risks of Internet communication, including harassment, exploitation, and excessive use, and to insist that teenagers follow Internet safety rules (see [www.safeteens.com](http://www.safeteens.com)).

**Friendship and Adjustment.** As long as adolescent friendships are high in trust, intimate sharing, and support and not characterized by relational aggression or attraction to antisocial

behavior, they contribute to many aspects of psychological health and competence into early adulthood (Bagwell & Schmidt, 2011; Furman & Rose, 2015), for several reasons:

- *Close friendships provide opportunities to explore the self and develop a deep understanding of another.* Through open, honest communication, friends become sensitive to each other's strengths and weaknesses, needs and desires—a process that supports the development of self-concept, perspective taking, and identity.
- *Close friendships provide a foundation for future intimate relationships.* Conversations with teenage friends about sexuality and romance, along with the intimacy of friendship itself, may help adolescents establish and work out problems in romantic partnerships (Connolly & Goldberg, 1999).
- *Close friendships help young people deal with the stresses of adolescence.* By enhancing sensitivity to and concern for another, supportive friendships promote empathy, sympathy, and prosocial behavior. As a result, friendships contribute to involvement in constructive youth activities, avoidance of antisocial acts, and psychological well-being (Barry & Wentzel, 2006; Lansford et al., 2003).
- *Close friendships can improve attitudes toward and involvement in school.* Close friendships promote good school adjustment, academically and socially (Wentzel, Barry, & Caldwell, 2004). Teenagers who enjoy interacting with friends at school may begin to view all aspects of school life more positively.

### LOOK and LISTEN

Interview several adolescents about qualities they value most in their best friends. Ask how friendships have helped them cope with stress and resulted in other personal benefits.

## Cliques and Crowds

In early adolescence, *peer groups* (see Chapter 10) become increasingly common and tightly knit. They are organized into **cliques**—groups of about five to seven members who are friends and, therefore, usually resemble one another in family background, attitudes, values, and interests (Brown & Dietz, 2009). At first, cliques are limited to same-sex members. Among girls but not boys, being in a clique predicts academic and social competence. Clique membership is more important to girls, who use it as a context for expressing emotional closeness (Henrich et al., 2000). By midadolescence, mixed-sex cliques are common.

Among Western adolescents attending high schools with complex social structures, often several cliques with similar values form a larger, more loosely organized group called a **crowd**. Unlike the more intimate clique, membership in a crowd is based on reputation and stereotype, granting the adolescent an identity within the larger social structure of the school. Prominent crowds in typical North American and European high schools include “brains” (nonathletes who enjoy academics), “jocks” (who are very involved in sports), “populars” (class leaders with high peer

These high school drama club members form a crowd, establishing relationships on the basis of shared interests. Crowd membership grants them an identity within the larger social structure of the school.

acceptance), “partyers” (who value socializing but care little about schoolwork), “nonconformists” (who like unconventional clothing and music), “burnouts” (who frequently use alcohol and drugs, engage in sexual risk taking, and otherwise get into trouble), and “normals” (average to good students who get along with most other peers) (Stone & Brown, 1999; Sussman et al., 2007).

What influences the sorting of teenagers into cliques and crowds? Crowd affiliations are linked to strengths in adolescents' self-concepts, which reflect their abilities and interests (Prinstein & La Greca, 2002). Ethnicity also plays a role. Minority teenagers who associate with an ethnically defined crowd, as opposed to a crowd reflecting their abilities and interests, sometimes are motivated by discrimination in their school or neighborhood. Alternatively, they may be expressing a strong ethnic identity (Brown et al., 2008). Family factors are important, too. Negative relationships with parents that suppress adolescents' expression of autonomy predict difficulties in establishing favorable relationships and autonomy with peers (Allen & Loeb, 2015). As a result, teenagers are more likely to join peer groups that reject conventional values and promote risk-taking and rebellious behavior.

Once adolescents join a clique or crowd, it can modify their beliefs and behavior. In a Dutch longitudinal study, membership in nonconventional crowds (such as nonconformists and burnouts) predicted a rise in internalizing and externalizing problems (Doornwaard et al., 2012). Perhaps nonconventional youths respond with anxiety and depressive symptoms to feeling disliked by members of higher-status crowds. And within their own crowds, they experience frequent peer modeling and encouragement for antisocial activity.

Although conventional-crowd membership (brains, jocks, and populars) tends to be associated with better adjustment, the positive impact of having academically and socially skilled peers is greatest for teenagers whose own parents use an authoritative

style. And the negative impact of having antisocial, drug-using friends is strongest for teenagers whose parents use less effective child-rearing styles (Mounts & Steinberg, 1995). In sum, family experiences affect the extent to which adolescents become like their peers over time.

Among heterosexual teenagers, as interest in dating increases, boys' and girls' cliques come together. Mixed-sex cliques provide boys and girls with models of how to interact and a chance to do so without having to be intimate (Connolly et al., 2004). By late adolescence, when boys and girls feel comfortable enough about approaching each other directly, the mixed-sex clique disappears.

Crowds also decline in importance. As adolescents settle on personal values and goals, they no longer feel a need to broadcast, through dress, language, and preferred activities, who they are. From tenth to twelfth grade, many young people switch crowds, mostly in conventional directions (Doornwaard et al., 2012; Strouse, 1999). Brains, popular, and normal crowds grow and deviant crowds lose members as teenagers focus more on their future.

## Dating

The hormonal changes of puberty increase sexual interest, but cultural expectations determine when and how dating begins. Asian youths start dating later and have fewer dating partners than young people in Western societies, which tolerate and even encourage romantic involvements from middle school on (see Figure 12.2). At age 12 to 14, these relationships are usually casual, lasting only briefly. By age 16, they have become steady relationships, continuing, on average, for one to two years, though breakups remain common for about one-third (Carver, Joyner, & Udry, 2003; Manning et al., 2014). Early adolescents tend to mention recreation and achieving peer status as reasons

for dating. By late adolescence, as young people are ready for greater psychological intimacy, they look for dating partners who offer personal compatibility, companionship, affection, and social support (Collins & van Dulmen, 2006b; Meier & Allen, 2009).

The achievement of intimacy between dating partners typically lags behind that between friends. And positive relationships with parents and friends contribute to warm romantic ties, whereas conflict-ridden parent–adolescent and peer relationships forecast hostile dating interactions (Furman & Collins, 2009; Linder & Collins, 2005).

Recall from Chapter 6 that according to ethological theory, early attachment bonds lead to an *internal working model*, or set of expectations about attachment figures, that guides later close relationships. Consistent with these ideas, secure attachment to parents in infancy and childhood—together with recollections of that security in adolescence—predicts higher-quality teenage friendships and romantic ties (Collins & van Dulmen, 2006a; Collins, Welsh, & Furman, 2009).

Parents' marital interactions make a difference, too, likely through modeling important relationship skills. In longitudinal research, parents' approach to marital conflict resolution predicted teenagers' conflict resolution with friends 1 year later and with romantic partners up to 7 years later (Miga, Gdula, & Allen, 2012). Impressively, parents' marital conflict-resolution strategies also forecast qualities of young people's interactions with their own marital partners 17 years later (Whitton et al., 2008).

Perhaps because early adolescent romantic involvements are shallow and stereotyped, early dating is related to drug use, delinquency, and poor academic achievement (Miller et al., 2009). These factors, along with a history of uninvolved parenting and aggression in family and peer relationships, increase the likelihood of dating violence. About 10 to 20 percent of adolescents are physically or sexually abused by dating partners; boys and girls are equally likely to report being victims, and violence by one partner is often returned by the other (Narayan, England, & Egeland, 2013; Narayan et al., 2014). Mental health consequences are severe, including increased anxiety, depression, and suicide attempts in victims of both genders, plus antisocial behavior in boys and unhealthy weight control (vomiting and use of laxatives) in girls (Exner-Cortens, Eckenrode, & Rothman, 2012). Young teenagers are better off sticking with group activities, such as parties and dances, before becoming involved with a steady boyfriend or girlfriend.

Lesbian and gay youths face special challenges in initiating and maintaining visible romances. Recall from Chapter 11 that because of prejudice, sexual minority adolescents sometimes retreat into heterosexual dating. Although more are identifying their sexual orientation to others than in the past, many have difficulty finding a partner because their peers with same-sex romantic interests have not yet come out (Glover, Galliher, & Lamere, 2009). Similar to heterosexual youths, security of attachment to parents and friends predicts gratifying romantic ties among lesbian, gay, and bisexual adolescents (Starks, Newcomb, & Mustanski, 2015). And again, prediction from teenagers' attachments to parents is persistent, still evident in

**FIGURE 12.2 Increase in romantic relationships during adolescence.** More than 16,000 U.S. youths responded to an interview in which they indicated whether they had been involved in a romantic relationship during the past 18 months. At age 12, about one-fourth of young people reported romantic involvement, a figure that rose to about three-fourths at age 18. (Based on Carver, Joyner, & Udry, 2003; Connolly & McIsaac, 2011.)

This young Native American couple has been dating for about a week. In addition to enhancing the quality of other peer relationships, close romantic ties promote sensitivity, empathy, self-esteem, social support, and identity progress.

sexual minority couples' romantic relationship satisfaction in early adulthood.

After high school graduation, many adolescent romances dissolve, and those that survive usually become less satisfying (Connolly & McIsaac, 2011). Because young people are still forming their identities, high school couples often find that they have little in common later. Nevertheless, among older teenagers, close romantic ties promote sensitivity, empathy, self-esteem, social support, and identity progress. In addition, teenagers' increasing capacity for caring and compromise with dating partners enhances the quality of other peer relationships (Collins, Welsh, & Furman, 2009). Thus, as long as dating leads to warm, supportive romantic bonds, it fosters adjustment and provides beneficial lessons in relating to people generally.

## Ask yourself

**CONNECT** Discuss the many links between adolescents' parental and peer relationships.

**APPLY** Thirteen-year-old Mattie's parents are warm, firm in their expectations, and consistent in monitoring her activities. At school, Mattie met some girls who want her to tell her parents she's going to a friend's house and then, instead, join them at the beach for a party. Is Mattie likely to comply? Explain.

**REFLECT** What factors likely influenced your crowd membership in high school? How did crowd membership influence your values and behavior?

## Problems of Development

**12.8** Describe factors related to adolescent depression and suicide.

**12.9** Discuss factors related to delinquency.

Most young people move through adolescence with little disturbance. But as we have seen, some encounter major disruptions in development, such as early parenthood, substance abuse, and school failure. In each instance, biological and psychological changes, families, schools, peers, communities, and culture combine to yield particular outcomes. Serious difficulties rarely occur in isolation but are usually interrelated—as is apparent in three additional problems of the teenage years: depression, suicide, and delinquency.

## Depression

Depression—feeling sad, frustrated, and hopeless about life, accompanied by loss of pleasure in most activities and disturbances in sleep, appetite, concentration, and energy—is the most common psychological problem of adolescence. Among U.S. teenagers, 20 to 50 percent experience mild to moderate feelings of depression, bouncing back after a short time. More worrisome are the 15 to 20 percent who have had one or more major depressive episodes, a rate comparable to that of adults. About 5 percent are chronically depressed—gloomy and self-critical for many months and sometimes years (American Psychiatric Association, 2013; Tharpar et al., 2012).

Serious depression affects only 1 to 2 percent of children, who are far less likely than their adolescent counterparts to remain depressed when reassessed at older ages, including into adulthood (Carballo et al., 2011). In industrialized nations, depression increases sharply from ages 12 to 16. Teenage girls are twice as likely as boys to report persistent depressed mood—a difference sustained throughout the lifespan (Hyde, Mezulis, & Abramson, 2008).

If allowed to continue, depression seriously impairs social, academic, and vocational functioning. Unfortunately, the stereotypical view of adolescence as a period of storm and stress leads many adults to minimize the seriousness of adolescent depression, misinterpreting the despondency and irritability that accompany it as just a passing phase. As a result, the overwhelming majority of depressed teenagers do not receive treatment.

**Factors Related to Adolescent Depression.** The precise combination of biological and environmental factors leading to depression varies from one individual to the next. Twin studies indicate that depression is moderately heritable. Furthermore, the onset of depression in girls is more closely associated with the hormonal changes of puberty than with age (Angold et al., 1999). This suggests that the impact of estrogens on the adolescent brain is involved.

But pubertal hormone changes alone rarely trigger depression. Rather, genetic and hormonal risk factors seem to sensitize

© RICHARD CLARK/GETTY IMAGES

Depression in adolescence is often misinterpreted as just a passing phase. As a result, the overwhelming majority of depressed teenagers do not receive treatment.

the brain to react more strongly to stressful experiences (Natsuaki, Samuels, & Leve, 2014). In support of this view, mounting evidence indicates that the short 5-HTTLPR gene, which increases the likelihood of self-regulation difficulties (see page 194 in Chapter 6), is linked to adolescent depression, but only in the presence of negative life stressors (Karg et al., 2011; Li, Berk, & Lee, 2013). This gene–environment interaction operates more consistently in adolescent girls than in boys.

Although depression runs in families, recall from earlier chapters that depressed or otherwise stressed parents often engage in maladaptive parenting. As a result, their child’s attachment, emotional self-regulation, and self-esteem may be impaired, with serious consequences for cognitive and social skills (Yap, Allen, & Ladouceur, 2008). Depressed youths usually display a learned-helpless attributional style (see Chapter 10) (Graber, 2004). In a vulnerable young person, numerous negative life events may spark depression—for example, failing at something important, parental divorce, the end of a close friendship or romantic partnership, victimization through bullying, or other abusive experiences.

**Gender Differences.** Why are girls more prone to depression than boys? Besides greater stress reactivity, girls’ gender-typed coping styles—passivity, dependency, and tendency to ruminate on anxieties and problems—seem to be involved. In line with this explanation, adolescents who identify strongly with “feminine” traits ruminate more and tend to be more depressed, regardless of their sex (Lopez, Driscoll, & Kistner, 2009; Papadakis et al., 2006). In contrast, girls with either an androgynous or a “masculine” gender identity show low rates of depressive symptoms (Priess, Lindberg, & Hyde, 2009).

Having friends with depressive symptoms is linked to a rise in teenagers’ own depressive symptoms, perhaps because

corumination is high in such relationships (Conway et al., 2011). Girls who repeatedly feel overwhelmed by life challenges become even more physiologically reactive to stress and cope increasingly poorly (Hyde, Mezulis, & Abramson, 2008; Natsuaki, Samuels, & Leve, 2014). In this way, stressful experiences and stress reactivity feed on each other, sustaining depression.

Profound depression in adolescence predicts depression in adulthood and serious impairments in work, family life, and social life. And depression can lead to suicidal thoughts, which all too often are translated into action.

## Suicide

The U.S. suicide rate increases from childhood into middle adulthood, but it jumps sharply at adolescence. Currently, suicide is the third-leading cause of death among American youths, after motor vehicle collisions and homicides. Perhaps because U.S. teenagers experience more stress and fewer supports than in the past, the adolescent suicide rate tripled between the mid-1960s and mid-1990s. This was followed by a period of little change and, from the mid-2000s on, a slight increase (Centers for Disease Control and Prevention, 2015k, 2016d). At the same time, rates of adolescent suicide vary widely among industrialized nations—low in Greece, Italy, and Spain; intermediate in Australia, Canada, Japan, and the United States; and high in Finland, Ireland, New Zealand, Norway, and Russia (Patton et al., 2012; Värnik et al., 2012). These international differences remain unexplained.

**Factors Related to Adolescent Suicide.** Despite girls’ higher rates of depression, the number of boys who kill themselves exceeds the number of girls by a ratio of over 4 to 1. Boys have more risk factors for suicide, including substance abuse and aggression. Also, girls make more unsuccessful suicide attempts and use methods from which they are more likely to be revived, such as a sleeping pill overdose. In contrast, boys more often choose techniques that lead to instant death, such as firearms or hanging (Esposito-Smythers et al., 2014). Gender-role expectations may contribute; less tolerance exists for feelings of helplessness and failed efforts in males than in females.

Perhaps because of greater support from extended families, African Americans, Asian Americans, and Hispanics have slightly lower suicide rates than European Americans. Recently, however, suicide has risen among African-American adolescent boys; the current rate approaches that of European-American boys. And Native-American youths commit suicide at rates two to six times national averages (Centers for Disease Control and Prevention, 2015k). High rates of profound family poverty, school failure, alcohol and drug abuse, and depression probably underlie these trends.

Lesbian, gay, bisexual, and transgender youths also are at high risk, attempting suicide three times as often as other adolescents. Those who have tried to kill themselves report more family conflict, problems in romantic relationships, and peer victimization (Liu & Mustanski, 2012).

Suicide tends to occur in two types of young people. The first group includes adolescents who are highly intelligent but solitary,

withdrawn, and unable to meet their own standards or those of important people in their lives. Members of a second, larger group show antisocial tendencies and express their unhappiness through bullying, fighting, stealing, increased risk taking, and drug abuse (Spirito et al., 2012). Besides being hostile and destructive toward others, they turn their anger and disappointment inward.

Suicidal adolescents often have a family history of emotional and antisocial disorders and suicide, and they typically suffer from chronic depression, anxiety, and unresolved anger. In addition, they are likely to have experienced multiple stressful life events, including economic disadvantage, parental divorce, frequent parent–child conflict, and abuse and neglect. Stressors typically increase during the period preceding a suicide attempt or completion (Kaminski et al., 2010). Triggering events include parental blaming of the teenager for family problems, the breakup of an important peer relationship, or the humiliation of having been caught engaging in antisocial acts.

Public policies resulting in cultural disintegration have amplified suicide rates among Native-American youths. From the late 1800s to the 1970s, Native-American families were forced to enroll their children in government-run residential boarding schools designed to erase tribal affiliations. In these repressive institutions, children were not allowed to “be Indian” in any way—culturally, linguistically, artistically, or spiritually (Goldston et al., 2008). The experience left many young people academically unprepared and emotionally scarred, contributing to family and community disorganization in current and succeeding generations (Barnes, Josefovitz, & Cole, 2006; Howell & Yuille, 2004). Consequently, alcohol abuse, youth crime, and suicide rates escalated.

Why does suicide increase in adolescence? In addition to the rise in depressed mood, teenagers’ improved ability to plan ahead is a major factor. Although some act impulsively, many young people take purposeful steps toward killing themselves. Other cognitive changes also contribute. Belief in the personal fable (see Chapter 11) leads many depressed young people to conclude that no one could possibly understand their intense pain. As a result, despair, hopelessness, and isolation deepen.

**Prevention and Treatment.** To prevent suicides, parents and teachers must be trained to pick up on the signals that a troubled teenager sends (see Table 12.2). Schools and community settings, such as recreational and religious organizations, can help by strengthening adolescents’ connections with their cultural heritage and providing knowledgeable, approachable, and sympathetic adults, peer support groups, and information about telephone hot lines (Miller, 2011; Spirito et al., 2012). Once a teenager takes steps toward suicide, staying with the young person, listening, and expressing compassion and concern until professional help can be obtained are essential.

Treatments for depressed and suicidal adolescents range from antidepressant medication to individual, family, and group therapy. Until the adolescent improves, removing weapons, knives, razors, scissors, and drugs from the home is vital. On a broader scale, gun-control legislation that limits adolescents’ access to the most frequent and deadly suicide method in the

**TABLE 12.2**  
**Warning Signs of Suicide**

Efforts to put personal affairs in order—smoothing over troubled relationships, giving away treasured possessions
Verbal cues—saying goodbye to family members and friends, making direct or indirect references to suicide (“I won’t have to worry about these problems much longer”; “I wish I were dead”)
Feelings of sadness, despondency, “not caring” anymore
Extreme fatigue, lack of energy, boredom
No desire to socialize; withdrawal from friends and family
Easily frustrated
Volatile mood swings—spells of crying or laughing, angry outbursts
Inability to concentrate, distractibility
Decline in grades, absence from school, discipline problems
Neglect of personal appearance
Sleep change—loss of sleep or excessive sleepiness
Obtaining a weapon or other means of self-harm, such as prescription medications

United States would greatly reduce both the number of suicides and the high teenage homicide rate (Lewiecki & Miller, 2013).

After a suicide, family and peer survivors need support to help them cope with grief, anger, and guilt over not having been able to help the victim. Teenage suicides often occur in clusters, with one death increasing the likelihood of others among depressed peers who knew the young person or heard about the suicide through the media (Feigelman & Gorman, 2008). In view of this trend, an especially watchful eye must be kept on vulnerable adolescents after a suicide happens. Restraint by journalists in publicizing teenage suicides also aids prevention.

## Delinquency

Juvenile delinquents are children or adolescents who engage in illegal acts. Since the mid-1990s, youth crime has declined sharply in the United States. Currently, 12- to 17-year-olds account for about 9 percent of police arrests, one-third less than two decades ago (U.S. Department of Justice, 2015). Yet when asked directly and confidentially about lawbreaking, almost all teenagers admit to having committed some sort of offense—usually a minor crime, such as petty stealing or disorderly conduct (Flannery et al., 2003).

Police arrests and self-reports show that delinquency rises over adolescence and then declines from the early twenties on—a trend found in many Western countries (Eisner & Malti, 2015). Recall that antisocial behavior increases among teenagers as a result of heightened reward seeking and desire for peer approval. Over time, peers become less influential; decision

© MARIE-REINE MATTEVAU

Delinquency rises over adolescence and then declines. Teenagers commit more crimes in poverty-stricken neighborhoods where they have easy access to drugs, firearms, and deviant peers.

making, emotional self-regulation, and moral reasoning improve; and young people enter social contexts (such as higher education, work, marriage, and career) that are less conducive to lawbreaking.

For most adolescents, a brush with the law does not forecast long-term antisocial behavior. But repeated arrests are cause for concern. Teenagers are responsible for 11 percent of violent offenses in the United States (U.S. Department of Justice, 2015). A small percentage become recurrent offenders, who commit most of these crimes, and some enter a life of crime. As the Biology and Environment box on the following page reveals, childhood-onset conduct problems are far more likely to persist than conduct problems that first appear in adolescence.

**Factors Related to Delinquency.** In adolescence, the gender gap in physical aggression widens. Although girls account for about one in five adolescent arrests for violence, their offenses are largely limited to simple assault (such as pushing and spitting). Serious violent crime is mostly the domain of boys (U.S. Department of Justice, 2015). SES and ethnicity are strong predictors of arrests but only mildly related to teenagers' self-reports of antisocial acts. The difference is due to the tendency to arrest, charge, and punish low-SES ethnic minority youths more often than their higher-SES white and Asian counterparts (Farrington, 2009; Hunt, 2015).

Difficult temperament, low intelligence, poor school performance, peer rejection in childhood, and association with antisocial peers are linked to chronic delinquency (Laird et al., 2005). How do these factors fit together? One of the most consistent findings is that delinquent youths, regardless of ethnicity

and SES, experience parenting that is low in warmth, high in conflict, and characterized by harsh, inconsistent discipline and weak control and monitoring (Deutsch et al., 2012; Harris-McKoy & Cui, 2013). Because marital transitions often contribute to family discord and disrupted parenting, boys who experience parental separation and divorce are especially prone to delinquency (Farrington, 2009). And youth crime peaks on weekdays between 2:00 and 8:00 P.M., when many teenagers are unsupervised (U.S. Department of Justice, 2015).

Our discussion on pages 273–274 in Chapter 8 explained how ineffective parenting can promote and sustain children's aggression, with boys—who are more active and impulsive—more often targets of parental anger, physical punishment, and inconsistency. When these child temperamental traits combine with emotionally negative, inept parenting, aggression rises sharply during childhood, leads to violent offenses in adolescence, and persists into adulthood (again, see the Biology and Environment box).

Teenagers commit more crimes in poverty-stricken neighborhoods with poor-quality schools, limited recreational and employment opportunities, and high adult criminality (Leventhal, Dupéré, & Brooks-Gunn, 2009). In such neighborhoods, adolescents have easy access to deviant peers, drugs, and firearms and are likely to be recruited into antisocial gangs, whose members commit the vast majority of violent delinquent acts. Schools in these locales typically fail to meet students' developmental needs (Chung, Mulvey, & Steinberg, 2011). Large classes, weak instruction, rigid rules, and reduced academic expectations and opportunities are associated with higher rates of lawbreaking, even after other influences are controlled.

**Prevention and Treatment.** Because delinquency has roots in childhood and results from events in several contexts, prevention must start early and take place at multiple levels (Frey et al., 2009). Positive family relationships, authoritative parenting, high-quality teaching in schools, and communities with healthy economic and social conditions go a long way toward reducing adolescent antisocial acts.

Lacking resources for effective prevention, many U.S. schools have implemented *zero tolerance policies*, which severely punish all disruptive and threatening behavior, major and minor, usually with suspension or expulsion. Yet often these policies are implemented inconsistently: Low-SES minority students are two to three times as likely to be punished, especially for minor misbehaviors. No evidence exists that zero tolerance achieves its objective of reducing youth aggression and other forms of misconduct (Reppucci, Meyer, & Kostelnik, 2011; Teske, 2011). To the contrary, some studies find that by excluding students from school, zero tolerance heightens high school dropout and antisocial behavior.

Treating serious offenders requires an intensive, often lengthy approach, also directed at the multiple determinants of delinquency. The most effective interventions include training parents in communication, monitoring, and discipline strategies and providing youths with experiences that improve cognitive and social skills, moral reasoning, anger management, and

## Biology and Environment

### Two Routes to Adolescent Delinquency

**P**ersistent adolescent delinquency follows two paths of development, one involving a small number of youths with an onset of conduct problems in childhood, the second a larger number with an onset in adolescence. The early-onset type is far more likely to lead to a life-course pattern of aggression and criminality (Moffitt, 2007). The late-onset type usually does not persist beyond the transition to early adulthood.

Both childhood-onset and adolescent-onset youths engage in serious offenses; associate with deviant peers; participate in substance abuse, unsafe sex, and dangerous driving; and spend time in correctional facilities. Why does antisocial activity more often continue and escalate into violence in the first group?

Most research has focused on boys, but several investigations report that girls who were physically aggressive in childhood are also at risk for later problems—occasionally violent delinquency but more often other norm-violating behaviors and psychological disorders (Broidy et al., 2003; Chamberlain, 2003). Early relational aggression is linked to adolescent conduct problems as well.

#### Early-Onset Type

Early-onset youngsters usually inherit traits that predispose them to aggressiveness (Eisner & Malti, 2015). For example, violence-prone children (mostly boys) are emotionally negative, restless, willful, and physically aggressive as

early as age 2. They also show subtle deficits in cognitive functioning that seem to contribute to disruptions in language, executive function, emotional self-regulation, and morally relevant emotions of empathy and guilt (Malti & Krettenauer, 2013; Moffitt, 2007; Reef et al., 2011). Some have attention-deficit hyperactivity disorder (ADHD), which compounds their learning and self-control problems.

Yet most early-onset boys decline in aggression over time. Among those who follow the life-course path, harsh parenting transforms their undercontrolled style into defiance and persistent aggression (Beyers et al., 2003). As they fail academically and are rejected by peers, they befriend other deviant youths, who facilitate one another's violent behavior while relieving loneliness (see Figure 12.3) (Dodge et al., 2008; Hughes, 2010). Limited cognitive and social skills result in high rates of school dropout and unemployment, contributing further to antisocial involvements.

Children high in relational aggression also tend to be hyperactive, subjected to harsh parenting, and frequently in conflict with peers and adults (Spieker et al., 2012; Willoughby, Kupersmidt, & Bryant, 2001). As these behaviors trigger peer rejection, relationally aggressive girls befriend other girls high in relational hostility, and their aggression rises (Werner & Crick, 2004). Adolescents high in relational aggression are often angry and defiant of adult rules. Among teenagers who combine

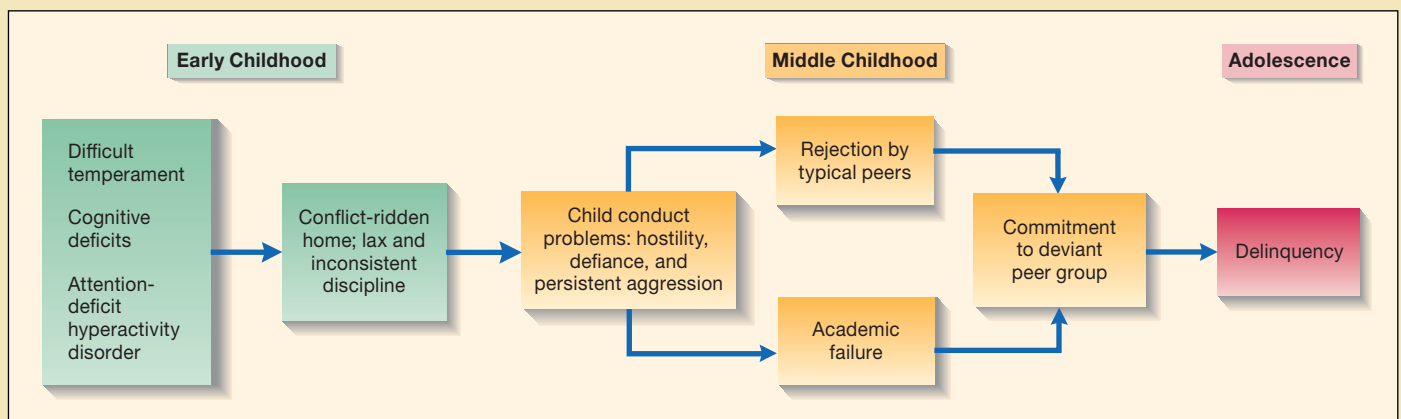

physical and relational hostility, these oppositional reactions intensify, increasing the likelihood of serious antisocial activity (Harachi et al., 2006; McEachern & Snyder, 2012).

#### Late-Onset Type

Other youths first display antisocial behavior around the time of puberty, gradually increasing their involvement. Their conduct problems arise from the peer context of early adolescence. For some, quality of parenting may decline for a time, perhaps due to family stresses or the challenges of disciplining an unruly teenager (Moffitt, 2007). When age brings gratifying adult privileges, these youths draw on prosocial skills mastered before adolescence and abandon their antisocial ways.

A few late-onset youths do continue to engage in antisocial acts. The seriousness of their adolescent offenses seems to trap them in situations that close off opportunities for responsible behavior. Being employed or in school and forming positive, close relationships predict an end to criminal offending by age 20 to 25 (Farrington, Ttofi, & Coid, 2009). In contrast, the longer antisocial young people spend in prison, the more likely they are to sustain a life of crime.

These findings suggest a need for a fresh look at policies aimed at stopping youth crime. Keeping youth offenders locked up for many years disrupts their educational and vocational lives and access to positive, caring relationships with adults during a crucial period of development (Bernstein, 2014). In this way, juvenile incarceration condemns them to a bleak future.

**FIGURE 12.3** Path to chronic delinquency for adolescents with childhood-onset antisocial behavior. Difficult temperament and cognitive deficits characterize many of these youths in early childhood; some have attention-deficit hyperactivity disorder. Inept parenting transforms biologically based self-control difficulties into hostility and defiance.

other aspects of emotional self-regulation (DiBiase et al., 2011; Heilbrun, Lee, & Cottle, 2005). Yet even these multidimensional treatments can fall short if young people remain embedded in hostile home lives, poor-quality schools, antisocial peer groups, and violent neighborhoods.

**FIGURE 12.4** Impact of multisystemic therapy on arrests and family-related civil suits 22 years after treatment. A follow-up of violent youths two decades after treatment revealed that, compared to participants receiving individual therapy, those assigned to multisystemic therapy had fewer criminal arrests overall, and the crimes they did commit were far less violent. Multisystemic therapy recipients also displayed reduced family instability. (Based on Sawyer & Borduin, 2011.)

In a program called *multisystemic therapy*, counselors combined family intervention with integrating violent youths into positive school, work, and leisure activities and disengaging them from deviant peers. Compared with conventional services or individual therapy, random assignment to the intervention led to improved parent–adolescent relationships and school performance, a dramatic drop in number of arrests that persisted for two decades after treatment, and—when participants did commit crimes—a reduction in their severity (see Figure 12.4). Multisystemic therapy also helped limit family instability once youth offenders reached adulthood, as measured by involvement in civil suits over divorce, paternity, or child support (Henggeler et al., 2009; Sawyer & Borduin, 2011). Efforts to create nonaggressive environments—at the family, community, and cultural levels—are needed to help delinquent youths and to foster healthy development of all young people.

## Ask yourself

**CONNECT** Why are adolescent girls at greater risk for depression and adolescent boys at greater risk for suicide?

**APPLY** Zeke had been well-behaved in elementary school, but at age 13 he started spending time with the “wrong crowd.” At 16, he was arrested for property damage. Is Zeke likely to become a long-term offender? Why or why not?

**REFLECT** During adolescence, did you or your friends engage in any lawbreaking acts? If so, at what age? Were you motivated by a desire for excitement and/or peer approval?

## Summary / chapter 12

### Erikson's Theory: Identity versus Role Confusion (p. 408)

#### 12.1 According to Erikson, what is the major personality attainment of adolescence?

- Erikson viewed **identity** as the major personality attainment of adolescence. Young people who successfully resolve the psychological conflict of **identity versus role confusion** construct a unified self-definition based on self-chosen values and goals.

### Self-Understanding (p. 408)

#### 12.2 Describe changes in self-concept and self-esteem during adolescence.

- Cognitive changes enable adolescents to develop more organized, consistent self-descriptions, with social, personal, and moral values as key themes.

- Self-esteem further differentiates and, for most adolescents, rises. Pubertal timing, academic performance, peer acceptance, parenting style, and the larger social environment all influence self-esteem.

#### 12.3 Describe the four identity statuses, along with factors that promote identity development.

- **Identity achievement** (exploration followed by commitment to values, beliefs, and goals) and **identity moratorium** (exploration without having reached commitment) are psychologically healthy identity statuses. Long-term **identity foreclosure** (commitment without exploration) and **identity diffusion** (lack of both exploration and commitment) are related to adjustment difficulties.

- An information-gathering cognitive style, healthy parental attachment, interaction with diverse peers, close friendships, and schools and communities offering rich and varied opportunities promote healthy identity development. Supportive families and communities can foster a strong, secure **ethnic identity** among minority adolescents, who often must overcome **acculturative stress**. A **bicultural identity** offers additional emotional and social benefits.

### Moral Development (p. 413)

#### 12.4 Describe Kohlberg's theory of moral development, and evaluate its accuracy.

- At Kohlberg's **preconventional level**, morality is externally controlled and actions are judged by their consequences; at the **conventional level**, conformity to laws and rules is regarded as necessary for positive human relationships and societal order; and at the **postconventional level**, morality is defined by abstract, universal principles.

- A reexamination of Kohlberg's stages suggests that moral maturity can be found at Stages 3 and 4; few people attain the post-conventional level. Because situational factors influence moral judgments, Kohlberg's stages are best viewed as loosely organized and overlapping.
- Contrary to Gilligan's claim, Kohlberg's theory does not underestimate the moral maturity of females but instead taps both justice and caring orientations.
- Compared with children, teenagers display more subtle reasoning about conflicts between personal choice and community obligation and are increasingly aware of the moral implications of following social conventions.

### 12.5 Describe influences on moral reasoning and its relationship to moral behavior.

- Factors contributing to moral maturity include warm, rational parenting, peer discussions of moral issues, and school environments with nondiscrimination policies. In village societies, where moral cooperation is based on direct relations between people, moral reasoning rarely moves beyond Kohlberg's Stage 3. In both village cultures and industrialized societies that value interdependence, moral dilemma responses are more other-directed than in Western societies.

- Maturity of moral reasoning is only modestly related to moral behavior. Moral behavior is also influenced by empathy and guilt, temperament, cultural experiences, and **moral identity**. Although formal religious involvement declines in adolescence, most religiously affiliated teenagers are advantaged in moral values and behavior.

- Researchers favoring a pragmatic approach to morality assert that moral maturity varies depending on context and motivations.

## The Family (p. 420)

### 12.6 Discuss changes in parent–child and sibling relationships during adolescence.

- In their quest for **autonomy**, adolescents rely more on themselves and less on parents for decision making. As teenagers deidealize their parents, they often question parental authority. Warm, supportive parenting that balances connection and separation, makes appropriate demands for maturity, and provides consistent monitoring predicts favorable outcomes.
- Sibling influence declines as adolescents separate from the family and turn toward peers. Still, attachment to siblings remains strong for most young people.

## Peer Relations (p. 422)

### 12.7 Describe adolescent friendships, peer groups, and dating relationships and their consequences for development.

- Adolescent friendships are based on intimacy, mutual understanding, and loyalty and contain more self-disclosure. Girls place greater emphasis on emotional closeness, boys on shared activities and accomplishments.
- Though online interaction can augment friendship, it also poses risks. Very high social media use is linked to unsatisfying face-to-face social experiences, and excessive Internet use amplifies adjustment difficulties.
- Adolescent friendships—when not characterized by relational aggression or attraction to antisocial behavior—promote self-concept, perspective taking, identity, and the capacity for intimate relationships. They also help young people deal with stress and can foster improved attitudes toward and involvement in school.
- Adolescent peer groups are organized into **cliques**, particularly important to girls, and **crowds**, which grant teenagers an identity within the larger social structure of the school. With interest in dating, mixed-sex cliques increase in importance. Both cliques and crowds diminish as teenagers settle on personal values and goals.

- Intimacy in dating relationships lags behind that between friends. Positive relationships with parents and friends contribute to secure romantic ties.

## Problems of Development (p. 427)

### 12.8 Describe factors related to adolescent depression and suicide.

- Depression is the most common psychological problem of adolescence, with girls at greater risk in industrialized nations. Combinations of biological and environmental factors are implicated, including heredity, maladaptive parenting, a learned-helpless attributional style, and negative life events.
- The suicide rate increases sharply at adolescence. Although teenage girls make more unsuccessful suicide attempts, boys account for more deaths. Teenagers at risk for suicide may be withdrawn but more often are antisocial. Family turmoil is common in the backgrounds of suicidal adolescents.

### 12.9 Discuss factors related to delinquency.

- Delinquency rises over adolescence and then declines. But only a few teenagers are serious repeat offenders—usually boys with a childhood history of conduct problems.
- A family environment low in warmth, high in conflict, and characterized by inconsistent discipline and low monitoring is consistently related to delinquency, as are poverty-stricken neighborhoods with high crime rates and ineffective schools.

## Development in Adolescence

DEREK TRASK/ALAMY

### EARLY ADOLESCENCE: 11–14

#### Physical

- If a girl, reaches peak of growth spurt. (369)
- If a girl, adds more body fat than muscle. (369)
- If a girl, starts to menstruate. (371–372)
- If a boy, begins growth spurt. (369)
- If a boy, starts to ejaculate seminal fluid. (372)
- If a sexual minority, awareness of sexual orientation emerges. (382)
- If a girl, motor performance increases gradually, leveling off by age 14. (370)
- Reacts more strongly to stressful events; shows heightened sensation-seeking and risk-taking behavior. (373–374)
- Sleep “phase delay” strengthens. (374)

#### Cognitive

- Gains in hypothetico-deductive reasoning and propositional thought. (389–390)
- Gains in scientific reasoning—coordinating theory with evidence—on complex, multivariable tasks. (391)

LAURA DWIGHT PHOTOGRAPHY

- Becomes more self-conscious and self-focused. (392–393)
- Becomes more idealistic and critical. (393)
- Improves in executive function, metacognition, and cognitive self-regulation. (373–374, 390–392)

#### Emotional/Social

- Self-concept includes abstract descriptors unifying separate personality traits, but these are not interconnected and are often contradictory. (408)
- Moodiness and parent–child conflict tend to increase. (375–376, 420–421)
- In striving for autonomy, spends less time with parents and siblings and more time with peers. (422)

DAVID GROSSMAN/ALAMY

- Friendships decline in number and are based on intimacy, mutual understanding, and loyalty. (422–423)
- Peer groups become organized into same-sex cliques. (425)
- In high schools with complex social structures, cliques with similar values form crowds. (425)

### MIDDLE ADOLESCENCE: 14–16

#### Physical

- If a girl, completes growth spurt. (369)
- If a boy, reaches peak of growth spurt. (369)
- If a boy, voice deepens. (372)
- If a boy, adds muscle while body fat declines. (369)
- If a boy, motor performance improves dramatically. (370)
- May be sexually active. (380–381)
- If a sexual minority boy, is likely certain of sexual orientation. (382)

#### Cognitive

- Continues to improve in hypothetico-deductive reasoning and propositional thought. (389–390)

ELLEN B. SEMISI

- Continues to improve in executive function, metacognition, and cognitive self-regulation (373–374, 390–392).
- Continues to improve in scientific reasoning, following a similar sequence of mastery on different types of tasks. (391–392)
- Becomes less self-conscious and self-focused. (386–387)
- Improves in decision making. (393–394)

## Emotional/Social

- Combines features of the self into an organized self-concept. (408)
- Self-esteem differentiates further and tends to rise. (408–409)
- In many cases, begins to move from lower to higher identity statuses. (409–410)
- Increasingly emphasizes ideal reciprocity and societal laws as the basis for resolving moral dilemmas. (414–415)

MYRLEEN FERGUSSON CATE/PHOTOEDIT

- Engages in more subtle reasoning about conflicts between moral, social-conventional, and personal-choice issues. (416)
- Mixed-sex cliques become common. (425–426)
- Has probably started dating. (426)

## LATE ADOLESCENCE: 16–18

### Physical

- If a boy, completes growth spurt. (369)
- If a boy, gains in motor performance continue. (370)

ALAMY

- If a sexual minority girl, is likely certain of sexual orientation. (382)

### Cognitive

- Continues to improve in executive function, metacognition, cognitive self-regulation, and scientific reasoning. (373–374, 390–392)
- Improves in decision making. (393–394)

CINDY CHARLES/PHOTOEDIT

## Emotional/Social

- Self-concept emphasizes personal and moral values. (408)
- Continues to construct an identity, typically moving to higher identity statuses. (409–410)
- Continues to advance in maturity of moral reasoning; motivation to act morally increases. (414–415, 418)
- Cliques and crowds decline in importance. (426)
- Seeks psychological intimacy in romantic ties, which last longer. (426–427)

The back seat and trunk piled high with belongings, 23-year-old Sharese hugged her mother and brother goodbye, jumped in the car, and headed toward the interstate with a sense of newfound freedom mixed with apprehension. Three months earlier, the family had watched proudly as Sharese received her bachelor's degree in chemistry from a small university 40 miles from her home. Her college years had been a time of gradual release from economic and psychological dependency on her family. She returned home periodically on weekends and lived there during the summer months. Her mother supplemented Sharese's loans with a monthly allowance. But this day marked a turning point. She was moving to her own apartment in a city 800 miles away, with plans to work on a master's degree. With a teaching assistantship and a student loan, Sharese felt more "on her own" than at any previous time in her life.

During her college years, Sharese made lifestyle changes and settled on a vocational direction. Overweight throughout high school, she lost 20 pounds in her sophomore year, revised her diet, and began an exercise regimen by joining the university's Ultimate Frisbee team, eventually becoming its captain. A summer spent as a counselor at a camp for chronically ill children helped convince Sharese to apply her background in science to a career in public health.

Still, two weeks before she was to leave, Sharese confided in her mother that she had doubts about her decision. "Sharese," her mother advised, "we never know if our life choices are going to suit us just right, and most times they aren't perfect. It's what we make of them—how we view and mold them—that turns them into successes." So Sharese embarked on her journey and found herself face-to-face with a multitude of exciting challenges and opportunities.

In this chapter, we take up the physical and cognitive sides of early adulthood, which extends from ages 18 to 40. As noted in Chapter 1, the adult years are difficult to divide into discrete periods because the timing of important milestones varies greatly among individuals—much more so than in childhood and adolescence. But for most people, early adulthood involves a common set of tasks: leaving home, completing education, beginning full-time work, attaining economic independence, establishing a long-term sexually and emotionally intimate relationship, and starting a family. These are energetic decades filled with momentous decisions that, more than any other time of life, offer the potential for living to the fullest. ●

© MARTY HETTNER/THE IMAGE WORKS

## PHYSICAL DEVELOPMENT

Throughout childhood and adolescence, the body grows larger and stronger, coordination improves, and sensory systems gather information more effectively. Once body structures reach maximum capacity and efficiency, **biological aging**, or **senescence**, begins—genetically influenced declines in the functioning of organs and systems that are universal in all members of our species. Like physical growth, however, biological aging varies widely across parts of the body, and individual differences are great—variation that the *lifespan perspective* helps us understand. A host of contextual factors—including each person’s genetic makeup, lifestyle, living environment, and historical period—can accelerate or slow age-related declines (Arking, 2006). As a result, the physical changes of the adult years are, indeed, *multidimensional* and *multidirectional* (see page 8 in Chapter 1).

In the following sections, we examine the process of biological aging. Then we turn to physical and motor changes already under way in early adulthood. As you will see, biological aging can be modified substantially through behavioral and environmental interventions. During the twentieth century, improved nutrition, medical treatment, sanitation, and safety added 25 to 30 years to *average life expectancy* in industrialized nations, a trend that is continuing (see Chapter 1, page 7). We will take up life expectancy in greater depth in Chapter 17.

### Biological Aging Is Under Way in Early Adulthood

**13.1** Describe current theories of biological aging, both at the level of DNA and body cells and at the level of tissues and organs.

At an intercollegiate tournament, Sharese dashed across the playing field, leaping high to catch Frisbees sailing her way. In her early twenties, she is at her peak in strength, endurance, sensory acuteness, and immune system responsiveness. Yet over the next two decades, she will age and, as she moves into middle and late adulthood, will show more noticeable declines. Biological aging is the combined result of many causes, some operating at the level of DNA, others at the level of cells, and still others at the level of tissues, organs, and the whole organism. Despite hundreds of theories and the efforts of many researchers, our understanding of the mechanisms of biological aging is incomplete.

### Aging at the Level of DNA and Body Cells

Current explanations of biological aging at the level of DNA and body cells are of two types: (1) those that emphasize the *programmed effects of specific genes* and (2) those that emphasize the *cumulative effects of random events* that damage genetic and cellular material. Support for both views exists, and a combination may eventually prove to be correct.

© MOODBOARD/ALAMY

This whitewater kayaker, in his early twenties, is at his peak in strength, endurance, and sensory acuteness.

Genetically programmed aging receives some support from kinship studies indicating that longevity is a family trait. People whose parents had long lives tend to live longer themselves. And greater similarity exists in the lifespans of identical than fraternal twins. But the heritability of longevity is low to moderate, ranging from .15 to .50 for age at death and from .15 to .55 for various measures of current biological age, such as hand-grip muscle strength, respiratory capacity, blood pressure, bone density, and overall physical health (Dutta et al., 2011; Finkel et al., 2014). Rather than inheriting longevity directly, people probably inherit risk and protective factors, which influence their chances of dying earlier or later.

One “genetic programming” theory proposes the existence of “aging genes” that control biological changes, such as menopause, efficiency of gross motor skills, and deterioration of body cells. The strongest evidence for this view comes from research showing that human cells allowed to divide in the laboratory have a lifespan of 50 divisions, plus or minus 10 (Hayflick, 1998). With each duplication, a special type of DNA called **telomeres**—located at the ends of chromosomes, serving as a

© DE VISU/ALAMY

A young adult takes a selfie with her 85-year-old grandmother. Longevity tends to run in families, though people probably inherit risk and protective factors rather than length of life directly.

## Biology and Environment

### Telomere Length: A Marker of the Impact of Life Circumstances on Biological Aging

In the not-too-distant future, your annual physical exam may include an assessment of the length of your *telomeres*—DNA at the ends of chromosomes—which safeguard the stability of your cells. Telomeres shorten with each cell duplication; when they drop below a critical length, the cell can no longer divide and becomes senescent (see Figure 13.1). Although telomeres shorten with age, the rate at which they do so varies greatly. An enzyme called *telomerase* prevents shortening and can even reverse the trend, lengthening telomeres and protecting the aging cell.

Over the past decade, research examining the influence of life circumstances on telomere length has exploded. A well-established finding is that chronic illnesses, such as cardiovascular disease and cancer, hasten telomere shortening in white blood cells, which play a vital role in the immune response (see page 443) (Corbett & Alda, 2015). Telomere shortening, in turn, predicts more rapid disease progression and earlier death.

Accelerated telomere shortening has been linked to a variety of unhealthy behaviors, including cigarette smoking, excessive alcohol use, and the physical inactivity and overeating that lead to obesity and to insulin resistance, which often precedes type 2 diabetes (Epel et al., 2006; Ludlow, Ludlow, & Roth, 2013). Unfavorable health conditions may alter telomere length as early as the prenatal period, with possible long-term negative consequences for biological aging. In research on rats, poor maternal nutrition during pregnancy resulted in low birth weight and development of shorter telomeres in kidney and heart tissue (Tarry-Adkins et al., 2008). In related human investigations, children and adolescents who

had been low-birth-weight had shorter telomeres in their white blood cells than did their normal-birth-weight agemates (Raqib et al., 2007; Strohmaier et al., 2015).

Persistent emotional stress—in childhood, abuse, bullying, or exposure to family violence; in adulthood, parenting a child with a chronic illness, caring for an older adult with dementia, or experiences of racial discrimination or violence—is linked to telomere shortness in white blood cells and swabbed cheek cells (Chae et al., 2014; Drury et al., 2014; Price et al., 2013; Shalev et al., 2013). In other research, maternal severe emotional stress during pregnancy predicted shortened telomere length in children’s white blood cells at birth and in follow-ups in early adulthood, even after other possible contributing factors (such as low birth weight and childhood and adult stress levels) were controlled (Entringer et al., 2011, 2012).

Fortunately, when adults make positive lifestyle changes, telomeres respond accordingly. Healthy eating behaviors; physical activity that increases fitness; reduced alcohol intake and cigarette smoking; and a decline in emotional stress are all associated with gains in telomerase activity and longer telomeres (Lin, Epel, & Blackburn, 2012; Shalev et al., 2013).

Currently, researchers are working on identifying sensitive

periods of telomere change—times when telomeres are most susceptible to modification. Early intervention—for example, enhanced prenatal care and treatments aimed at reducing childhood obesity and exposure to stressors—may be particularly powerful. But telomeres are changeable through intervention well into late adulthood (Epel et al., 2009; Price et al., 2013). As our understanding of predictors and consequences of telomere length expands, it may become an important index of health and aging throughout life.

**FIGURE 13.1** Telomeres at the ends of chromosomes.

(a) Telomeres in a newly created cell. (b) With each cell duplication, telomeres shorten; when too short, they expose DNA to damage, and the cell dies.

“cap” to protect the ends from destruction—shortens. Eventually, so little remains that the cells no longer duplicate at all. Telomere shortening acts as a brake against somatic mutations (such as those involved in cancer), which become more likely as cells duplicate. But an increase in the number of senescent cells (ones with short telomeres) also contributes to age-related disease, loss of function, and earlier mortality (Epel et al., 2009; Tchkonja et al., 2013). As the Biology and Environment box above reveals,

researchers have begun to identify health behaviors and psychological states that accelerate telomere shortening—powerful biological evidence that certain life circumstances compromise longevity.

According to an alternative, “random events” theory, DNA in body cells is gradually damaged through spontaneous or externally caused mutations. As these accumulate, cell repair and replacement become less efficient, and abnormal cancerous cells

are often produced. Animal studies confirm an increase in DNA breaks and deletions and damage to other cellular material with age. Similar evidence is accruing for humans (Freitas & Magalhães, 2011).

One hypothesized cause of age-related DNA and cellular abnormalities is the release of **free radicals**—naturally occurring, highly reactive chemicals that form in the presence of oxygen. When oxygen molecules break down within the cell, the reaction strips away an electron, creating a free radical. As it seeks a replacement from its surroundings, it destroys nearby cellular material, including DNA, proteins, and fats essential for cell functioning, thereby increasing the individual’s vulnerability to wide-ranging disorders of aging, including cardiovascular disease, neurological impairments, cancer, cataracts, and arthritis (Stohs, 2011). Genes for longevity, some researchers have speculated, might work by defending against free radicals.

But mounting evidence indicates that free radicals are not a major contributor to DNA mutations, cellular damage, and reduced longevity. To the contrary, in some species, elevated free-radical activity—as long as it does not reach toxic levels—is associated with longer life, likely because it serves as a “stress signal” that activates DNA repair systems within cells (Shokolenko, Wilson, & Alexeyev, 2014). These findings may explain why antioxidant dietary supplements, such as vitamin A, beta-carotene, and vitamin E, have consistently failed to reduce the incidence of disease or extend length of life (Bjelakovic, Nikolova, & Gluud, 2013).

Furthermore, scientists have identified certain species with reduced genetic defenses against free-radical activity but with exceptional longevity (Liu, Long, & Liu, 2014). The naked mole rat, the longest-living rodent, has a lifespan of up to 31 years, despite displaying greater age-related DNA damage in some of its organs than seen in the ordinary mouse, which lives no more than 4 years.

In sum, although free-radical damage increases with age, no clear evidence indicates that it triggers biological aging. Rather, it may at times contribute to longevity.

## Aging at the Level of Tissues and Organs

What consequences might age-related DNA and cellular deterioration have for the overall structure and functioning of organs and tissues? There are many possibilities. Among those with clear support is the **cross-linkage theory of aging**. Over time, protein fibers that make up the body’s connective tissue form bonds, or links, with one another. When these normally separate fibers cross-link, tissue becomes less elastic, leading to many negative outcomes, including loss of flexibility in the skin and other organs, clouding of the lens of the eye, clogging of arteries, and damage to the kidneys (Diggs, 2008; Kragstrup, Kjaer, & Mackey, 2011). Like other aspects of aging, cross-linking can be reduced by external factors, including regular exercise and a healthy diet.

Gradual failure of the endocrine system, which produces and regulates hormones, is yet another route to aging. An obvious example is decreased estrogen production in women, which culminates in menopause. Because hormones affect many body functions, disruptions in the endocrine system can have widespread effects on health and survival. For example, a gradual drop in growth hormone (GH) is associated with loss of muscle and bone mass, addition of body fat, thinning of the skin, and decline in cardiovascular functioning. In adults with abnormally low levels of GH, hormone therapy can slow these symptoms, but it has serious side effects, including increased risk of fluid retention in tissues, muscle pain, and cancer (Ceda et al., 2010; Sattler, 2013). So far, diet and physical activity are safer ways to limit these aspects of biological aging.

Finally, declines in immune system functioning contribute to many conditions of aging, including increased susceptibility to infectious disease and cancer, changes in blood vessel walls associated with cardiovascular disease, and chronic inflammation of body tissues, which leads to tissue damage and plays a role in many diseases. Decreased vigor of the immune response seems to be genetically programmed, but other aging processes we have considered (such as weakening of the endocrine system) can intensify it (Alonso-Fernández & De la Fuente, 2011; Franceschi & Campisi, 2014). Indeed, combinations of theories—the ones just reviewed as well as others—are needed to explain the complexities of biological aging. With this in mind, let’s turn to physical signs and other characteristics of aging.

## Physical Changes

**13.2** Describe the physical changes of aging, paying special attention to the cardiovascular and respiratory systems, motor performance, the immune system, and reproductive capacity.

During the twenties and thirties, changes in physical appearance and declines in body functioning are so gradual that most are hardly noticeable. Later, they will accelerate. The physical changes of aging are summarized in Table 13.1. We will examine several here and take up others in later chapters. Before we begin, let’s note that these trends are derived largely from cross-sectional studies. Because younger cohorts have experienced better health care and nutrition, cross-sectional evidence can exaggerate impairments associated with aging. Fortunately, longitudinal evidence is expanding, helping to correct this picture.

## Cardiovascular and Respiratory Systems

During her first month in graduate school, Sharese pored over research articles on cardiovascular functioning. In her African-American extended family, her father, an uncle, and three aunts had died of heart attacks in their forties and fifties. These

**TABLE 13.1**  
**Physical Changes of Aging**

ORGAN OR SYSTEM	TIMING OF CHANGE	DESCRIPTION
Sensory		
Vision	From age 30	As the lens stiffens and thickens, ability to focus on close objects declines. Yellowing of the lens, weakening of muscles controlling the pupil, and clouding of the vitreous (gelatin-like substance that fills the eye) reduce light reaching the retina, impairing color discrimination and night vision. Visual acuity, or fineness of discrimination, decreases, with a sharp drop between ages 70 and 80.
Hearing	From age 30	Sensitivity to sound declines, especially at high frequencies but gradually extending to all frequencies. Change is more than twice as rapid for men as for women.
Taste	From age 60	Sensitivity to the four basic tastes—sweet, salty, sour, and bitter—is reduced as number and distribution of taste buds on the tongue decline.
Smell	From age 60	Loss of smell receptors reduces ability to detect and identify odors.
Touch	Gradual	Loss of touch receptors reduces sensitivity on the hands, particularly the fingertips.
Cardiovascular	Gradual	As the heart muscle becomes more rigid, maximum heart rate decreases, reducing the heart's ability to meet the body's oxygen requirements when stressed by exercise. As artery walls stiffen and accumulate plaque, blood flow to body cells is reduced.
Respiratory	Gradual	Under physical exertion, respiratory capacity decreases and breathing rate increases. Stiffening of connective tissue in the lungs and chest muscles makes it more difficult for the lungs to expand to full volume.
Immune	Gradual	Shrinking of the thymus limits maturation of T cells and disease-fighting capacity of B cells, impairing the immune response.
Muscular	Gradual	As nerves stimulating them die, fast-twitch muscle fibers (responsible for speed and explosive strength) decline in number and size to a greater extent than slow-twitch fibers (which support endurance). Tendons and ligaments (which transmit muscle action) stiffen, reducing speed and flexibility of movement.
Skeletal	Begins in the late thirties, accelerates in the fifties, slows in the seventies	Cartilage in the joints thins and cracks, leading bone ends beneath it to erode. New cells continue to be deposited on the outer layer of the bones, and mineral content of bone declines. The resulting broader but more porous bones weaken the skeleton and make it more vulnerable to fracture. Change is more rapid in women than in men.
Reproductive	In women, accelerates after age 35; in men, begins after age 40	Fertility problems (including difficulty conceiving and carrying a pregnancy to term) and risk of having a baby with a chromosomal disorder increase.
Nervous	From age 50	Brain weight declines as neurons lose water content and die, mostly in the cerebral cortex, and as ventricles (spaces) within the brain enlarge. Development of new synapses and limited generation of new neurons can, in part, compensate for these declines.
Skin	Gradual	Epidermis (outer layer) is held less tightly to the dermis (middle layer); fibers in the dermis and hypodermis (inner layer) thin; fat cells in the hypodermis decline. As a result, the skin becomes looser, less elastic, and wrinkled. Change is more rapid in women than in men.
Hair	From age 35	Grays and thins.
Height	From age 50	Loss of bone strength leads to collapse of disks in the spinal column, leading to a height loss of as much as 2 inches by the seventies and eighties.
Weight	Increases to age 50; declines from age 60	Weight change reflects a rise in fat and a decline in muscle and bone mineral. Since muscle and bone are heavier than fat, the resulting pattern is weight gain followed by loss. Body fat accumulates on the torso and decreases on the extremities.

Sources: Arking, 2006; Feng, Huang, & Wang, 2013; Lemaitre et al., 2012.

tragedies prompted Sharese to enter the field of public health in hopes of finding ways to relieve health problems among black Americans. The prevalence of *hypertension*, or high blood pressure, is 13 percent higher in the U.S. black than in the U.S. white population; the African-American rate of death from heart

disease (the number one cardiovascular cause) is 40 percent higher (Mozaffarian et al., 2015).

Sharese was surprised to learn that fewer age-related changes occur in the heart than we might expect, given that heart disease is a leading cause of death throughout adulthood,

responsible for as many as 10 percent of U.S. male and 5 percent of U.S. female deaths between ages 20 and 34—figures that more than double in the following decade and, thereafter, continue to rise steadily with age (Mozaffarian et al., 2015). In healthy individuals, the heart's ability to meet the body's oxygen requirements under typical conditions (as measured by heart rate in relation to volume of blood pumped) does not change during adulthood. Only during stressful exercise does heart performance decline with age—a change due to a decrease in maximum heart rate and greater rigidity of the heart muscle (Arking, 2006). Consequently, the heart has difficulty delivering enough oxygen to the body during high activity and bouncing back from strain.

One of the most serious diseases of the cardiovascular system is *atherosclerosis*, in which heavy deposits of plaque containing cholesterol and fats collect on the walls of the main arteries. If present, it usually begins early in life, progresses during middle adulthood, and culminates in serious illness. Atherosclerosis is multiply determined, making it hard to separate the contributions of biological aging from individual genetic and environmental influences. The complexity of causes is illustrated by research indicating that before puberty, a high-fat diet produces only fatty streaks on the artery walls (Oliveira, Patin, & Escrivao, 2010). In sexually mature adults, however, it leads to serious plaque deposits, suggesting that sex hormones may heighten the insults of a high-fat diet.

Cardiovascular disease has decreased considerably since the mid-twentieth century, with a larger drop during the past two decades due to a decline in cigarette smoking, improved diet and exercise among at-risk individuals, and better medical detection and treatment of high blood pressure and cholesterol (Mozaffarian et al., 2015). And as a longitudinal follow-up of an ethnically diverse sample of U.S. black and white 18- to 30-year-olds revealed, those at low risk—defined by not smoking, normal body weight, healthy diet, and regular physical activity—were far less likely to be diagnosed with symptoms of heart disease over the succeeding two decades (Liu et al., 2012). Later, when we consider health and fitness, we will see why heart attacks were so common in Sharese's family—and why they occur at especially high rates in the African-American population.

Like the heart, the lungs show few age-related changes in functioning at rest, but during physical exertion, respiratory volume decreases and breathing rate increases with age. Maximum vital capacity (amount of air that can be forced in and out of the lungs) declines by 10 percent per decade after age 25. Connective tissue in the lungs, chest muscles, and ribs stiffens with age, making it more difficult for the lungs to expand to full volume (Lowery et al., 2013; Wilkie et al., 2012). Fortunately, under normal conditions, we use less than half our vital capacity. Nevertheless, aging of the lungs contributes to older adults' difficulty in meeting the body's oxygen needs while exercising.

## Motor Performance

Declines in heart and lung functioning under conditions of exertion, combined with gradual muscle loss, lead to changes in

motor performance. In most people, the impact of biological aging on motor skills is difficult to separate from decreases in motivation and practice. Therefore, researchers study competitive athletes, who try to attain their very best performance in real life (Tanaka & Seals, 2008). As long as athletes continue intensive training, their attainments at each age approach the limits of what is biologically possible.

Many athletic skills peak between ages 20 and 35, then gradually decline. In several investigations, the mean ages for best performance of Olympic and professional athletes in a variety of sports were charted over time. Absolute performance in most events improved over the past century. Athletes continually set new world records, suggesting improved training methods. But ages of best performance remained relatively constant. Athletic tasks that require speed of limb movement, explosive strength, and gross-motor coordination—sprinting, jumping, and tennis—typically peak in the early twenties. Those that depend on endurance, arm-hand steadiness, and aiming—long-distance running, baseball, and golf—usually peak in the late twenties and early thirties (Morton, 2014; Schulz & Curnow, 1988). Because these skills require either stamina or precise motor control, they take longer to perfect.

Research on outstanding athletes tells us that the upper biological limit of motor capacity is reached in the first part of early adulthood. How quickly do athletic skills weaken in later years? Longitudinal research on master runners reveals that as long as practice continues, speed drops only slightly from the mid-thirties into the sixties, when performance falls off at an accelerating pace (see Figure 13.2) (Tanaka & Seals, 2003, 2008; Trappe, 2007). In the case of long-distance triathlon performance, which combines

**FIGURE 13.2** Ten-kilometer running times with advancing age, based on longitudinal performances of hundreds of master athletes.

Runners maintain their speed into the mid-thirties, followed by modest increases in running times into the sixties, with a progressively steeper increase thereafter. (From H. Tanaka & D. R. Seals, 2003, "Dynamic Exercise Performance in Masters Athletes: Insight into the Effects of Primary Human Aging on Physiological Functional Capacity," *Journal of Applied Physiology*, 5, p. 2153. © The American Physiological Society (APS). All rights reserved. Adapted with permission.)

MICHAEL KAPPELER/PICTURE-ALLIANCE/DPA/AP IMAGES

These professional athletes, ranging in age from 21 to 30 years, compete for the title of 2015 world champion in the men's 200-meter finals. Sprinting, which requires speed of limb movement and explosive strength, typically peaks in the early twenties.

running, swimming, and cycling, the decline in speed is even more gradual: The accelerating performance drop-off is delayed until the seventies, due to its non-weight-bearing swimming and cycling components (Lepers, Knechtle, & Stapley, 2013).

Indeed, sustained training leads to adaptations in body structures that minimize motor declines. For example, vital capacity is one-third greater in both younger and older active sports participants than in healthy, inactive age-mates (Zaccagni, Onisto, & Gualdi-Russo, 2009). Training also slows muscle loss, increases speed and force of muscle contraction, and leads fast-twitch muscle fibers to be converted into slow-twitch fibers, which support excellent long-distance running performance and other endurance skills (Faulkner et al., 2007). In a study of hundreds of thousands of amateur marathon competitors, 25 percent of the 65- to 69-year-old runners were faster than 50 percent of the 20- to 54-year-old runners (Leyk et al., 2010). And in exceptional instances, outstanding older athletes show startling performance gains with age. For example, in the Ironman Triathlon World Championship, the top male finisher in the 70- to 74-year-old age group in 2010 improved his 2012 performance by nearly an hour (Lepers, Knechtle, & Stapley, 2013). Modest gains have even been observed among 80-year-old competitors.

In sum, although athletic skills are at their best in early adulthood, biological aging accounts for only a small part of age-related declines until advanced old age. Lower levels of performance by healthy people into their sixties and seventies largely reflect reduced capacities resulting from adaptation to a less physically demanding lifestyle.

## Immune System

The immune response is the combined work of specialized cells that neutralize or destroy antigens (foreign substances) in the body. Two types of white blood cells play vital roles. *T cells*,

which originate in the bone marrow and mature in the thymus (a small gland located in the upper part of the chest), attack antigens directly. *B cells*, manufactured in the bone marrow, secrete antibodies into the bloodstream that multiply, capture antigens, and permit the blood system to destroy them. Because receptors on their surfaces recognize only a single antigen, T and B cells come in great variety. They join with additional cells to produce immunity.

The capacity of the immune system to offer protection against disease increases through adolescence and declines after age 20. The trend is partly due to changes in the thymus, which is largest during the teenage years, then shrinks until it is barely detectable by age 50. As a result, production of thymic hormones is reduced, and the thymus is less able to promote full maturity and differentiation of T cells (Denkinger et al., 2015). Because B cells release far more antibodies when T cells are present, the immune response is compromised further.

Withering of the thymus is not the only reason that the body gradually becomes less effective in warding off illness. The immune system interacts with the nervous and endocrine systems. For example, psychological stress can weaken the immune response. During final exams, Sharese was less resistant to colds. And in the month after her father died, she had great difficulty recovering from the flu. Conflict-ridden relationships, caring for an ill aging parent, sleep deprivation, and chronic depression can also reduce immunity. And physical stress—from pollution, allergens, poor nutrition, and rundown housing—undermines immune functioning throughout adulthood (Cruces et al., 2014; Fenn, Corona, & Godbout, 2014). When physical and psychological stressors combine, the risk of illness is magnified.

## Reproductive Capacity

Sharese was born when her mother was in her early twenties. At the same age a generation later, Sharese was embarking on several years of graduate school, prioritizing education and career. Many people believe that pregnancy during the twenties is ideal, not only because of lower risk of miscarriage and chromosomal disorders (see Chapter 2) but also because younger parents have more energy to keep up with active children. Nevertheless, as Figure 13.3 on the following page reveals, first births to women in their thirties have increased greatly over the past three decades. Many people are delaying childbearing until their education is complete, their vocational lives are well-established, and they know they can support a child.

Nevertheless, reproductive capacity does decline with age. Between ages 15 and 29, 11 percent of U.S. married childless women report fertility problems, a figure that rises to 14 percent among 30- to 34-year-olds, 39 percent among 35- to 39-year-olds, and 47 percent among 40- to 44-year-olds. Recall, also, that after 35, the success of reproductive technologies drops sharply with age (see page 52 in Chapter 2) (Chandra, Copen, & Stephen, 2013). Because the uterus shows no consistent changes from the late thirties through the forties, the decline in female fertility is

**FIGURE 13.3** First births to American women of different ages in 1970 and 2014. The birthrate decreased for women 20 to 24 years of age, whereas it increased for women 25 years of age and older. For women in their thirties, the birthrate increased sixfold, and for those in their early forties, it doubled. Similar trends have occurred in other industrialized nations. (Based on Hamilton et al., 2015.)

largely due to reduced number and quality of ova. In many mammals, including humans, a certain level of reserve ova in the ovaries is necessary for conception (American College of Obstetricians and Gynecologists, 2014; Balasch, 2010). Some women have normal menstrual cycles but do not conceive because their reserve of ova is too low.

In males, semen volume and sperm motility decrease gradually after age 35, contributing to reduced fertility. In addition, the percentage of abnormal sperm rises, which elevates miscarriage rates and diminishes the success of reproductive technologies, irrespective of maternal age (Belloc et al., 2014). Although there is no best time in adulthood to begin parenthood, individuals who postpone childbearing until their late thirties or their forties risk having fewer children than they desired or none at all.

## Ask yourself

**CONNECT** How do heredity and environment jointly contribute to age-related changes in cardiovascular, respiratory, and immune system functioning?

**APPLY** Penny is a long-distance runner for her college track team. What factors will affect Penny's running performance 30 years from now?

**REFLECT** Before reading this chapter, had you thought of early adulthood as a period of aging? Why is it important for young adults to be aware of influences on biological aging?

## Health and Fitness

**13.3** Describe the influence of SES, nutrition, and exercise on health, and discuss obesity in adulthood.

**13.4** What are the most commonly abused substances, and what health risks do they pose?

**13.5** Describe sexual attitudes and behavior of young adults, and discuss sexually transmitted infections and sexual coercion.

**13.6** How does psychological stress affect health?

Figure 13.4 displays leading causes of death in early adulthood in the United States. Death rates for all causes exceed those of many other industrialized nations (OECD, 2015d). A combination of factors, including higher rates of poverty and extreme obesity, more lenient gun-control policies, and historical lack of universal health insurance in the United States, is likely responsible. In later chapters, we will see that homicide rates decline with age, while disease and physical disability rates rise. Biological aging clearly contributes to this trend. But, as we have noted, wide individual and group differences in physical changes are linked to environmental risks and health-related behaviors.

SES variations in health over the lifespan reflect these influences. With the transition from childhood to adulthood, health inequalities associated with SES increase; income, education, and occupational status show strong, continuous relationships with almost every disease and health indicator (Agigoroaei, 2016). Furthermore, SES largely accounts for the sizable health

**FIGURE 13.4** Leading causes of death between 25 and 44 years of age in the United States. Nearly half of unintentional injuries are motor vehicle accidents. As later chapters will reveal, unintentional injuries remain a leading cause of death at older ages, rising sharply in late adulthood. Rates of cancer and cardiovascular disease rise steadily during middle and late adulthood. Except for cancer, men are more vulnerable than women to each leading cause. From what you learned in earlier chapters, can you explain these sex differences? (Based on Heron, 2015.)

ROBYN BECK/AFP/GETTY IMAGES

SES variations in health in the United States—larger than in other industrialized nations—are due to diverse health-related circumstances and habits plus insufficient access to high-quality, affordable health care. This Los Angeles free clinic helps address these problems by offering preventive services, including eye exams, to over 1,200 patients per day.

advantage of white over ethnic minority adults in the United States (Phuong, Frank, & Finch, 2012). Consequently, improving socioeconomic conditions is essential for closing ethnic gaps in health.

Health-related circumstances and habits—stressful life events, crowding, pollution, diet, exercise, overweight and obesity, substance abuse, jobs with numerous health risks, and availability of supportive social relationships—underlie SES health disparities (Smith & Infurna, 2011). Furthermore, poor health in childhood, which is linked to low SES, affects health in adulthood. The overall influence of childhood factors lessens if SES improves. But in most instances, child and adult SES remain fairly consistent, exerting a cumulative impact that amplifies SES differences in health with age (Matthews & Gallo, 2011; Wickrama et al., 2015).

Why are SES variations in health and mortality larger in the United States than in other industrialized nations? Besides lack of universal health insurance, low-income and poverty-stricken U.S. families are financially less well-off than families classified in these ways in other countries (Avendano & Kawachi, 2014). In addition, SES groups in the United States experience greater inequalities in environmental factors that affect health, such as housing, pollution, education, and community services.

These findings reveal, once again, that the living conditions that nations and communities provide combine with those that

people create for themselves to affect physical aging. Because the incidence of health problems is much lower during the twenties and thirties than later on, early adulthood is an excellent time to prevent later problems. In the following sections, we take up a variety of major health concerns—nutrition, exercise, substance abuse, sexuality, and psychological stress.

## Nutrition

Bombarded with advertising claims and an extraordinary variety of food choices, adults find it increasingly difficult to make wise dietary decisions. An abundance of food, combined with a heavily scheduled life, means that most Americans eat because they feel like it or because it is time to do so rather than to maintain the body's functions (Donatelle, 2015). As a result, many eat the wrong types and amounts of food. Overweight and obesity and diets high in sugar, fat, and processed foods are widespread nutritional problems with long-term consequences for adult health.

**Overweight and Obesity.** In Chapter 9, we noted that obesity (a greater than 20 percent increase over average body weight, based on age, sex, and physical build) has increased dramatically in many Western nations, and it is on the rise in the developing world as well. Among adults, a body mass index (BMI) of 25 to 29 constitutes overweight, a BMI of 30 or greater (amounting to 30 or more excess pounds) constitutes obesity. The U.S. adult obesity rate has continued to climb, recently reaching 38 percent. Obesity is especially prevalent among certain ethnic minorities, including Native Americans (41 percent), Hispanics (43 percent), and African Americans (48 percent) (Ogden et al., 2014). More African-American and Hispanic women than men are affected.

Overweight—a less extreme but nevertheless unhealthy condition—affects an additional 34 percent of Americans. Combine the rates of overweight and obesity and the total, 72 percent, makes Americans the heaviest people in the world (OECD, 2015c; Ogden et al., 2014). Notice that the U.S. obesity rate exceeds its rate of overweight—a blatant indicator of the epidemic scale of the problem.

Recall from Chapter 9 that overweight children and adolescents are very likely to become overweight adults. But a substantial number of people show large weight gains in adulthood, most often between ages 25 and 50. And young adults who were already overweight or obese typically get heavier, leading obesity rates to rise steadily between ages 20 and 60 (Ogden et al., 2014). Among immigrants, rates of overweight and obesity increase with length of time in the United States (Singh & Linn, 2013). First-generation adults (U.S. born with immigrant parents) have much higher odds of becoming obese than their foreign-born counterparts.

**Causes and Consequences.** As noted in Chapter 9, heredity makes some people more vulnerable to obesity than others. But environmental pressures underlie the rising rates of obesity in

industrialized nations: With the decline in need for physical labor in the home and workplace, our lives have become more sedentary. Meanwhile, the average number of calories and amount of sugar and fat consumed by Americans rose over most of the twentieth and early twenty-first century, with a sharp increase after 1970 (Cohen, 2014). Since then, low-cost, calorie-dense convenience foods and portion-supersizing have become widespread; eating out has escalated with women's increased participation in the labor force; and physical activity has declined as adults spend more time in sedentary transportation, jobs, and leisure activities—driving to and from work; sitting throughout the day, often behind a computer; and watching, on average, four hours of TV per day.

Adding some weight between ages 25 and 50 is a normal part of aging because **basal metabolic rate (BMR)**, the amount of energy the body uses at complete rest, gradually declines as the number of active muscle cells (which create the greatest energy demand) drops off. But excess weight is strongly associated with serious health problems—including type 2 diabetes, heart disease, and many forms of cancer—and with early death (see page 297 in Chapter 9).

Furthermore, overweight adults suffer enormous social discrimination. Compared with their normal-weight agemates, they are less likely to find mates, be rented apartments, receive financial aid for college, or be offered jobs. And they report frequent mistreatment by family members, peers, co-workers, and health professionals (Ickes, 2011; Puhl, Heuer, & Brownell, 2010). Since the mid-1990s, discrimination experienced by overweight Americans has increased, with serious physical and mental health consequences. Weight stigma triggers anxiety, depression, and low self-esteem, which increase the likelihood that unhealthy eating behaviors will worsen. The more discrimination overweight people report, the greater their chances for becoming obese or—if already obese—remaining so (Sutin & Terracciano, 2013). The widespread but incorrect belief, perpetuated by the media, that obesity is a personal choice promotes negative stereotyping of obese persons.

**Treatment.** Because obesity climbs in early and middle adulthood, treatment for adults should begin as soon as possible—preferably in the early twenties. Even moderate weight loss reduces health problems substantially (Poobalan et al., 2010). But successful intervention is difficult. Most individuals who start a weight-loss program return to their original weight, and sometimes to a heavier weight, within two years (Wadden et al., 2012). The high rate of failure is partly due to limited evidence on just how obesity disrupts the complex neural, hormonal, and metabolic factors that maintain a normal body-weight set point. Until more information is available, researchers are examining the features of treatments and participants linked to greater success. The following elements promote lasting behavior change:

- *A lifestyle change to a nutritious diet lower in calories, plus regular exercise.* To lose weight and maintain the loss, Sharese sharply reduced calories in her diet and exercised regularly. The precise balance of dietary protein, carbohydrate,

and fats that best helps adults lose weight is a matter of heated debate. Although scores of diet books offer different recommendations, no clear-cut evidence exists for the long-term superiority of one approach over others (Wadden et al., 2012). Calorie reduction rather than dietary composition predicts weight loss, though restricting sugar and fat yields substantial health benefits.

A permanent lifestyle alteration that restricts calorie intake while increasing physical activity is essential for countering a genetic tendency toward overweight. The weight regain experienced by most dieters is sharply reduced when high levels of regular, sustained physical activity (such as an hour per day of brisk walking) become part of their lifestyle (Kushner, 2012). But most people mistakenly believe that only temporary lifestyle changes are needed (MacLean et al., 2011).

- *Training participants to keep an accurate record of food intake and body weight.* About 30 to 35 percent of obese people are convinced they eat less than they do. And although they have continued to gain weight, American adults generally report weight losses—suggesting that they are in denial about the seriousness of their weight condition (Wetmore & Mokdad, 2012). Furthermore, about 30 percent have problems with binge eating—a behavior associated with weight-loss failure (Pacanowski et al., 2014).

As Sharese recognized how often she ate when not actually hungry and regularly recorded her weight, she was better able to limit food intake. Following a diet that prescribes

AP PHOTO/THE DAILY RECORD, MAXIMILIAN FRANZ

A young adult has her weight checked by a nutrition counselor near the end of a 90-day weight-loss program. Keeping an accurate record of food intake and body weight is an important element in losing weight and keeping it off.

portion-controlled servings to help control intake is associated with considerably greater weight loss (Kushner, 2012).

- **Social support.** Group or individual counseling and encouragement from friends and relatives help sustain weight-loss efforts by fostering self-esteem and self-efficacy (Poobalan et al., 2010). Once Sharese decided to act, with the support of her family and a weight-loss counselor, she felt better about herself even before the first pounds were shed.
- **Teaching problem-solving skills.** Most overweight adults do not realize that because their body has adapted to overweight, difficult periods requiring high self-control and patience are inevitable in successful weight loss (MacLean et al., 2011). Acquiring cognitive and behavioral strategies for coping with tempting situations and periods of slowed progress is associated with long-term change (Poelman et al., 2014). Weight-loss maintainers are more likely than individuals who relapse to be conscious of their behavior, to use social support, and to confront problems directly.
- **Extended intervention.** Longer treatments (from 25 to 40 weeks) that include the components listed here grant people time to develop new habits.

Although many Americans on weight-reduction diets are overweight, an estimated 25 to 65 percent of normal-weight adults view themselves as too heavy and are trying to lose weight (Nissen & Holm, 2015). Recall from Chapter 11 that the high value placed on thinness creates unrealistic expectations about desirable body weight and contributes to anorexia, bulimia, and binge eating disorder, which remain common in early adulthood (see pages 378–379). Throughout adulthood, both underweight and obesity are associated with increased mortality (Cao et al., 2014). A sensible body weight—neither too low nor too high—predicts physical and psychological health and longer life.

**Dietary Fat.** During college, Sharese altered the diet of her childhood and adolescent years, sharply limiting red meat, eggs, butter, and fried foods. The federal government’s Dietary Guidelines for Americans recommend that no more than 10 percent of total caloric intake be made up of saturated fat, which generally comes from meat and dairy products and is solid at room temperature (U.S. Department of Agriculture, 2016). No dietary limits are placed on healthy, unsaturated fats, found in most types of vegetable oil.

Research indicates that saturated fat, especially from meat, plays a role in the age-related rise in cardiovascular disease, breast cancer, and colon cancer (Ferguson, 2010; Sieri et al., 2014). In contrast, consuming unsaturated fat, especially in the form of linoleic acid—which is plentiful in corn, soybean, and safflower oils and in nuts and seeds—is linked to reduced cardiovascular disease mortality (Guasch-Ferré et al., 2015; Wu et al., 2014).

When we consume excessive saturated fat, some is converted to cholesterol, which accumulates as plaque on the arterial walls in atherosclerosis. Earlier in this chapter, we noted that atherosclerosis is determined by multiple biological and environmental factors. But saturated fat consumption (along with other

**FIGURE 13.5** Dietary fat and prevalence of high blood pressure among Africans in West Africa, the Caribbean, and the United States.

The three regions represent the historic path of the slave trade and, therefore, have genetically similar populations. As dietary fat increases, high blood pressure and heart disease rise. Both are particularly high among African Americans. (Based on Luke et al., 2001.)

societal conditions) is an important contributor to the high rate of heart disease in the U.S. black population. As Figure 13.5 shows, when researchers compared Africans in West Africa, the Caribbean, and the United States (the historic path of the slave trade), dietary fat increased, and so did high blood pressure and heart disease (Luke et al., 2001). In a survey of a large sample of inner-city African Americans experiencing financial and other stressors, those who consumed foods lower in fat said that neighborhood availability and affordability influenced their dietary choices (Eyler et al., 2004).

A vital goal of public health strategies aimed at improving nutrition and reducing the risk of chronic diseases is inducing people to replace saturated fat with unsaturated fat and with complex carbohydrates (whole grains, fruits, and vegetables), which are beneficial to cardiovascular health and protective against colon cancer (Kaczmarczyk, Miller, & Freund, 2012). Furthermore, regular exercise can reduce the harmful influence of saturated fat because it creates chemical byproducts that help eliminate cholesterol from the body.

## Exercise

Three times a week over the noon hour, Sharese delighted in running, making her way to a wooded trail that cut through a picturesque area of the city. Regular exercise kept her fit and slim, and she noticed that she caught fewer respiratory illnesses than in previous years, when she had been sedentary and overweight. As Sharese explained to a friend, “Exercise gives me a positive outlook and calms me down. Afterward, I feel a burst of energy that gets me through the day.”

Although most Americans are aware of the health benefits of exercise, only 50 percent of young adults engage in the nationally recommended 150 minutes per week of at least moderately intense leisure-time physical activity. And just 24 percent engage in the recommended two sessions per week of resistance exercises, which place a moderately stressful load on each of the major muscle groups. In early adulthood, about 40 percent of Americans are inactive, with no regular brief sessions of even light activity (U.S. Department of Health and Human Services, 2015d). More women than men are inactive. And inactivity is greater among low-SES adults, who live in less safe neighborhoods, have more health problems, experience less social support for exercising regularly, and feel less personal control over their health. Overweight and obesity along with self-reported poor health are strong predictors of inactivity, irrespective of SES (Valle et al., 2015). Yet increasing physical activity is one of the most powerful means of enhancing general health.

### LOOK and LISTEN

Contact your local parks and recreation department to find out what community supports and services exist to increase adult physical activity. Are any special efforts made to reach low-SES adults?

Besides reducing body fat and building muscle, exercise fosters resistance to disease. Frequent bouts of moderate-intensity exercise enhance the immune response, lowering the risk of colds or flu and promoting faster recovery from these illnesses (Donatelle, 2015). Furthermore, physical activity is linked to reduced incidence of several types of cancer, with the strongest findings for breast and colon cancer (Fedewa et al., 2015). Physically active people are also less likely to develop diabetes and cardiovascular disease (Mehanna, Hamik, & Josephson, 2016). If they do, these illnesses typically occur later and are less severe than among their inactive agemates.

How does exercise help prevent these serious illnesses? First, it reduces the incidence of obesity—a risk factor for heart disease, diabetes, and cancer. In addition, people who exercise probably adopt other healthful behaviors, thereby lowering the risk of diseases associated with high-fat diets, alcohol consumption, and smoking. In animal studies, exercise directly inhibits growth of cancerous tumors—beyond the impact of diet, body fat, and the immune response (de Lima et al., 2008). Exercise also promotes cardiovascular functioning by strengthening the heart muscle, decreasing blood pressure, and producing a form of “good cholesterol” (high-density lipoproteins, or HDLs) that helps remove “bad cholesterol” (low-density lipoproteins, or LDLs) from the artery walls (Donatelle, 2015).

Yet another way that exercise guards against illness is through its mental health benefits. Physical activity reduces anxiety and depression and improves mood, alertness, and energy. Furthermore, EEG and fMRI evidence indicates that exercise enhances neural activity in the cerebral cortex, and it improves overall cognitive functioning (Etnier & Labban, 2012; Kim et al.,

© HERO IMAGES INC./ALAMY

Regular exercise of at least moderate intensity predicts a healthier, longer life. These young adults doing box jumps as part of a fitness program reap both physical and mental health benefits.

2012). The impact of exercise on a “positive outlook,” as Sharese expressed it, is most obvious just after a workout and can last for several hours (Acevedo, 2012). The stress-reducing properties of exercise undoubtedly strengthen immunity to disease. And as physical activity enhances cognitive functioning and psychological well-being, it promotes on-the-job productivity, self-esteem, ability to cope with stress, and life satisfaction.

When we consider the evidence as a whole, it is not surprising that physical activity is associated with substantially lower death rates from all causes. The contribution of exercise to longevity cannot be accounted for by preexisting illness in inactive people. In a Danish longitudinal study of a nationally representative sample of 7,000 healthy 20- to 79-year-olds followed over several decades, mortality was lower among those who increased their leisure-time physical activity from low to either moderate or high than among those who remained consistently inactive (Schnohr, Scharling, & Jensen, 2003).

## Substance Abuse

Alcohol and drug use peaks among U.S. 19- to 25-year-olds and then declines steadily with age. Eager to try a wide range of experiences before settling down to the responsibilities of adulthood, young people of this age are more likely than younger or older individuals to smoke cigarettes, chew tobacco, use marijuana, and take stimulants to enhance cognitive or physical performance (U.S. Department of Health and Human Services, 2015a). Binge drinking, driving under the influence, and experimentation with prescription drugs (such as OxyContin, a highly addictive painkiller) and “party drugs” (such as LSD and MDMA, or Ecstasy, and new substances produced to mimic their effects) also increase, at times with tragic consequences. Risks include brain damage, lasting impairments in cognitive and emotional functioning, and liver, kidney, and heart failure resulting in death (Karila et al., 2015; National Institute on Drug Abuse, 2016a).

Furthermore, when alcohol and drug taking become chronic, they intensify the psychological problems that underlie addiction. As many as 16 percent of 19- to 25-year-olds are substance abusers, with similar rates of men and women seeking treatment (U.S. Department of Health and Human Services, 2014, 2015). Return to Chapter 11, pages 386–387, to review factors that lead to alcohol and drug abuse in adolescence. The same personal and situational conditions are predictive in the adult years. Tobacco, marijuana, and alcohol are the most commonly abused substances.

**Tobacco and Marijuana.** Dissemination of information on the harmful effects of cigarette smoking has helped reduce its prevalence among U.S. adults from 40 percent 50 years ago to 17 percent today (Centers for Disease Control and Prevention, 2015d). Still, smoking has declined very slowly, and most of the drop is among college graduates, with far less change among those who did not finish high school. Furthermore, more men than women smoke, but the gender gap is much smaller today than in the past, reflecting a sharp increase in smoking among young women who did not finish high school.

Although college students' cigarette smoking has decreased over the past 15 years, their use of other forms of tobacco (e-cigarettes and cigars) and, especially, of marijuana has risen (Johnston et al., 2014). Young people seem to have absorbed messages about the health risks of cigarettes, though they minimize the dangers of alternative tobacco sources. And because of legalization of recreational marijuana use in some U.S. states, many young people view marijuana as safe. Yet 30 percent of users experience problematic withdrawal symptoms that result in dependency (National Institute on Drug Abuse, 2016b). And moderate to high marijuana use predicts becoming a chronic cigarette smoker in early adulthood (Brook, Lee, & Brook, 2015).

Compared to marijuana, tobacco use is much more addictive. Of young people who smoke cigarettes, the overwhelming majority started before age 21 (U.S. Department of Health and Human Services, 2015a). And the earlier they began smoking, the greater their daily cigarette use and likelihood of continuing, an important reason that preventive efforts with adolescents and young adults are vital.

The ingredients of cigarette smoke—nicotine, tar, carbon monoxide, and other chemicals—leave their damaging mark throughout the body. As smokers inhale, oxygen delivery to tissues is reduced, and heart rate and blood pressure rise. Over time, exposure to toxins and insufficient oxygen result in damage to the retina of the eye; constriction of blood vessels leading to painful vascular disease; skin abnormalities, including premature aging, poor wound healing, and hair loss; decline in bone mass; decrease in reserve ova, uterine abnormalities, and earlier menopause in women; and reduced sperm count and higher rate of sexual impotence in men (Carter et al., 2015; Dechanet et al., 2011). Other deadly outcomes include increased risk of heart attack, stroke, acute leukemia, melanoma, and cancer of the mouth, throat, larynx, esophagus, lungs, stomach, pancreas, kidneys, and bladder.

Cigarette smoking is the single most important preventable cause of death in industrialized nations. One out of every three young people who become regular smokers will die from a smoking-related disease, and the vast majority will suffer from at least one serious illness (Adhikari et al., 2009). The chances of premature death rise with earlier age of smoking initiation and number of cigarettes consumed. At the same time, the benefits of quitting in early adulthood include return of most disease risks to near-nonsmoker levels within 1 to 10 years. In a study of 1.2 million British women, those who had been regular smokers but stopped before they reached age 30 avoided 97 percent of the elevated risk of premature death from cigarettes. And those who quit before age 40 avoided 90 percent of the added risk (Pirie et al., 2013). Continuing to smoke throughout adulthood reduced life expectancy by 11 years.

Nearly 70 percent of U.S. smokers report having tried to quit during the past year, though just half who saw their doctors in the past year received advice to do so (Centers for Disease Control and Prevention, 2015o; Danesh, Paskett, & Ferketich, 2014). Although millions have stopped without help, those who use cessation aids (for example, nicotine gum, nasal spray, or patches, designed to reduce dependency gradually) or enter treatment programs often fail: As many as 90 percent start smoking again within six months (Jackson et al., 2015). Unfortunately, too few treatments last long enough, effectively combine counseling with medications that reduce nicotine withdrawal symptoms, and teach skills for avoiding relapse.

**Alcohol.** National surveys reveal that about 9 percent of men and 5 percent of women in the United States are heavy drinkers, defined as weekly consumption of 15 drinks or more for men and 8 drinks or more for women (U.S. Department of Health and Human Services, 2015a). About one-third of heavy drinkers are *alcoholics*—people who cannot limit their alcohol use.

Alcohol consumption peaks in the late teens and early twenties and then declines steadily with age. Excessive use is particularly high among 18- to 22-year-old college students: 14 percent report heavy drinking and 39 percent binge drinking during the past month, compared with 9 and 33 percent for other people of the same age (National Institute on Alcohol Abuse and Alcoholism, 2015). Alcoholism usually begins during this age range and worsens over the following decade.

Rates of heavy drinking are similar for male and female college students, though women tend to “mature out” of harmful levels of use later than men (Hoepfner et al., 2013). Women also progress more quickly than men to alcohol dependence, in part because their bodies metabolize alcohol more slowly and, therefore, they experience alcohol-related problems at lower drinking levels. Also, whereas men more often drink to enhance positive emotions in social situations, women more often do so in response to stress and negative mood (Brady & Lawson, 2012). As we will see, consuming alcohol to dull awareness of life's problems is more strongly linked to sustained and increased use.

Twin and adoption studies support a moderate genetic contribution to alcoholism. Genes affecting alcohol metabolism and those promoting impulsivity and sensation seeking

(temperamental traits linked to alcohol and other addictions) are involved (Iyer-Eimerbrink & Nurnberger, 2014). But half of alcoholics have no family history of problem drinking.

Alcoholism crosses SES and ethnic lines but is higher in some groups than others. In cultures where alcohol is a traditional part of religious or ceremonial activities, people are less likely to abuse it. Where access to alcohol is carefully controlled and viewed as a sign of adulthood, dependency is more likely—factors that may, in part, explain why college students drink more heavily than young people not enrolled in college (Slutske et al., 2004). Poverty, hopelessness, and a history of physical or sexual abuse in childhood are among factors that sharply increase the risk of excessive drinking (Donatelle, 2015; U.S. Department of Health and Human Services, 2015a).

Alcohol acts as a depressant, impairing the brain's ability to control thought and action. In a problem drinker, it relieves anxiety at first but then induces it as the effects wear off, so the person drinks again, often at higher levels. Chronic alcohol use does widespread physical damage. Its best-known complication is liver disease, but it is also linked to cardiovascular disease, inflammation of the pancreas, irritation of the intestinal tract, bone marrow problems, disorders of the blood and joints, and some forms of cancer. Over time, alcohol causes brain damage, leading to confusion, apathy, inability to learn, and impaired memory (O'Connor, 2012). The costs to society are enormous. About one-third of fatal motor vehicle crashes in the United States involve drivers who have been drinking (U.S. Department of Transportation, 2014). Nearly half of convicted felons are alcoholics, and about half of police activities in large cities involve alcohol-related offenses (McKim & Hancock, 2013). Alcohol frequently plays a part in sexual coercion, including date rape, and in domestic violence.

The most successful treatments combine personal and family counseling, group support, and aversion therapy (use of medication that produces a physically unpleasant reaction to alcohol, such as nausea and vomiting). Alcoholics Anonymous, a

community support approach, helps many people exert greater control over their lives through the encouragement of others with similar problems. Nevertheless, breaking an addiction that has dominated a person's life is difficult; about 50 percent of alcoholics relapse within a few months (Kirshenbaum, Olsen, & Bickel, 2009).

## Sexuality

At the end of the teenage years, nearly 70 percent of U.S. young people have had sexual intercourse; by age 25, nearly all have done so, and the link between sexual activity and economic disadvantage apparent in adolescence (see page 381 in Chapter 11) has diminished (Copen, Chandra, & Febo-Vazquez, 2016). Compared with earlier generations, contemporary adults display a wider range of sexual choices and lifestyles, including non-marital experiences, cohabitation, marriage, and orientation toward a heterosexual or same-sex partner. In this chapter, we explore the attitudes, behaviors, and health concerns that arise as sexual activity becomes a regular event in young people's lives. In Chapter 14, we focus on the emotional side of close relationships.

**Heterosexual Attitudes and Behavior.** One Friday evening, Sharese accompanied her roommate Heather to a young singles bar, where two young men soon joined them. Faithful to her boyfriend, Ernie, whom she had met in college and who worked in another city, Sharese remained aloof for the next hour. In contrast, Heather was talkative and gave one of the men, Rich, her phone number. The next weekend, Heather went out with Rich. On the second date, they had intercourse, but the romance lasted only a few weeks. Aware of Heather's more adventurous sex life, Sharese wondered whether her own was normal. Only after several months of dating exclusively had she and Ernie slept together.

Since the 1950s, public displays of sexuality in movies and the media have steadily increased, fostering the impression that Americans are more sexually active than ever before. What are contemporary adults' sexual attitudes and behaviors really like? Answers were difficult to find until interviews addressing U.S. adults' sex lives first began to be conducted in the late 1980s with large, nationally representative samples. Today, the U.S. federal government regularly gathers such information from samples as large as 10,000 to 30,000 participants (Copen, Chandra, & Febo-Vazquez, 2016; Smith et al., 1972–2014). Additional, smaller-scale survey research has also enhanced our knowledge.

Recall from Chapter 11 that the sex lives of most teenagers do not dovetail with exciting media images. Similarly, although their sexual practices are diverse, adults are far less sexually active than we have come to believe. Monogamous, emotionally committed couples like Sharese and Ernie are more typical (and more satisfied) than couples like Heather and Rich.

Sexual partners, whether dating, cohabiting, or married, tend to be similar in age (within five years), education, ethnicity,

Although online dating sites have become increasingly popular, direct social interaction is vital for assessing one's compatibility with a potential partner.

and (to a lesser extent) religion. In addition, people who establish lasting relationships often meet in conventional ways—through friends or family members, or at school or social events where people similar to themselves congregate (Sprecher et al., 2015). The powerful influence of social networks on sexual choice is adaptive. Sustaining an intimate relationship is easier when adults share interests and values and people they know approve of the match.

Over the past decade, the Internet has become an increasingly popular way to initiate relationships. Among a sample of 2,200 Americans, 11 percent said they had used online dating sites or mobile dating apps. One-fourth of these had met their spouse or a long-term partner in this way, making the Internet the second most common route to meeting a partner, just behind meeting through friends. Furthermore, nearly 30 percent of participants knew someone who had formed an enduring relationship through Internet dating (Pew Research Center, 2013b). Knowing someone who has successfully met a partner online strongly predicts single adults' willingness to engage in Internet dating (Sprecher, 2011). Young people between 25 and 34 are the most avid users of dating sites and apps; 20 percent report having used them.

Nevertheless, online dating services sometimes undermine, rather than enhance, the chances of forming a successful relationship. Relying on Internet profiles and online communication omits aspects of direct social interaction that are vital for assessing one's compatibility with a potential partner. Especially when online communication persists for a long time (six weeks or more), people form idealized impressions that often lead to disappointment at face-to-face meetings (Finkel et al., 2012). Furthermore, having a large pool of potential partners from which to choose can promote a persistent "shopping mentality," which reduces online daters' willingness to make a commitment (Heino, Ellison, & Gibbs, 2010). Finally, the

techniques that matching sites claim to use to pair partners—sophisticated analyses of information daters provide—have not demonstrated any greater success than conventional off-line means of introducing people.

Consistent with popular belief, lifetime number of sexual partners (from age 18 on) reported by American adults has risen steadily over the past several decades, from an average of 7 in the late 1980s to 11 in the early 2010s, with men exceeding women by threefold—currently, 18 to 6. As Figure 13.6 shows, acceptance of premarital sex increased, with a sharp rise after the mid-2000s (Twenge, Sherman, & Wells, 2015). Nevertheless, when adults of any age are asked how many partners they have had in the past year, the usual reply—including from 18- to 25-year-olds—is one (Copen, Chandra, & Febo-Vazquez, 2016; Lefkowitz & Gillen, 2006).

What explains the trend toward more relationships in the context of sexual commitment? In the past, dating several partners was followed by marriage. Today, dating more often gives way to cohabitation, which typically leads either to marriage or to breakup. In addition, people are marrying later, and the divorce rate remains high. Together, these factors create more opportunities for new partners.

The college years are marked by an increase in uncommitted sexual encounters, including "hookups" (emotionally uninvolved, casual sex) and "friends with benefits" (casual sex as an add-on to an existing friendship). Estimates indicate that two-thirds or more of contemporary U.S. college students have experienced at least 1 hookup, and as many as one-fourth 10 or more (Halpern & Kaestle, 2014). Although some young people report positive reactions, these encounters often have negative emotional consequences (more so for women), including lower self-esteem, regret, and depressed mood (Lewis et al., 2012). The

**FIGURE 13.6** Percentage of U.S. adults agreeing that premarital sex and extramarital sex are “not wrong at all.” In surveys of nationally representative samples of many thousands of Americans age 18 and older over the past four decades, acceptance of premarital sex increased, rising sharply after the mid-2000s. In contrast, approval of extramarital sex remained consistently low, even showing a recent decline. (Based on Smith et al., 1972–2014.)

prevalence of casual sex on college campuses suggests that young people often use it to gratify sexual needs during a time in which they are not yet ready to invest in an intimate bond.

Still, the majority of U.S. 18- to 29-year-olds say they eventually want to settle down with a mutually exclusive lifetime sexual partner (Halpern & Kaestle, 2015). In line with this goal, most people spend the majority of their lives with one partner. And as Figure 13.6 reveals, approval of extramarital sex remains low among U.S. adults of all ages, even showing a slight recent decline.

How frequently do Americans have sex? Not nearly as often as the media would suggest. One-third of 18- to 59-year-olds have intercourse as often as twice a week, another third have it a few times a month, and the remaining third have it a few times a year or not at all. Three factors affect frequency of sexual activity: age, whether people are cohabiting or married, and how long the couple has been together. Single people have more partners, but this does not translate into more sex! Sexual activity increases through the twenties and (for men) the thirties as people either cohabit or marry. Then it declines, even though hormone levels have not changed much (Herbenick et al., 2010; Langer, 2004). The demands of daily life—working, commuting, taking care of home and children—are probably responsible. Despite the common assumption that sexual practices vary greatly across social groups, the patterns just described are unaffected by education, SES, or ethnicity.

Furthermore, sexual frequency predicts life satisfaction only in the context of a satisfying relationship. But beyond once a week, more frequent sex does not add to happiness (Muise, Schimmack, & Impett, 2015). Among adults in committed relationships, who range considerably in quantity of sexual activity, more than 80 percent report feeling “extremely physically and emotionally satisfied” with their sex lives, a figure that rises to 88 percent for married couples. In contrast, as number of sex partners increases, sexual satisfaction declines sharply (Paik, 2010). These findings challenge two stereotypes—that marriage is sexually dull and that people who engage in casual dating have the “hottest” sex.

A minority of U.S. adults—women more often than men—report persistent sexual problems. For women, the two most frequent difficulties are lack of interest in sex and inability to achieve orgasm. Most often mentioned by men are climaxing too early and anxiety about performance. Sexual difficulties are linked to an array of biological factors, including chronic illnesses such as atherosclerosis and diabetes and use of various drugs. They are also associated with low SES and psychological stress and are more common among people who are not married, have had many partners, and have experienced sexual abuse during childhood or sexual coercion in adulthood (Wincze & Weisberg, 2015). As these findings suggest, a history of unfavorable relationships and sexual experiences increases the risk of sexual dysfunction.

But overall, a completely untroubled physical experience is not essential for sexual happiness. Satisfying sex involves more than technique; it is attained in the context of love and fidelity. In sum, happiness with partnered sex is linked to an emotionally fulfilling relationship, good mental health, and overall contentment with life.

**Sexual Minority Attitudes and Behavior.** The majority of Americans support civil liberties and equal employment opportunities for lesbians, gay men, and bisexuals. And attitudes toward sex and romantic relationships between adults of the same sex have gradually become more accepting: Overall, more than half of U.S. adults favor allowing same-sex couples to marry legally—society’s official recognition of a sexual relationship (Pew Research Center, 2015f). As Figure 13.7 shows, members of the Millennial generation, born after 1980, are the most accepting of same-sex marriage, though acceptance has risen dramatically among all generations.

Sexual minorities’ political activism and greater openness about their sexual orientation have contributed to gains in acceptance. Exposure and interpersonal contact reduce negative attitudes; those who know many lesbian and gay people are highly accepting. Other than Millennials, who show no gender difference in acceptance, heterosexual men judge sexual minorities (especially gay men) more negatively than do heterosexual women, likely because of men’s greater concern with gender-role conformity (Clarke, Marks, & Lykins, 2015; Pew Research Center, 2010). Acceptance is greatest among highly educated people who are low in religiosity.

**FIGURE 13.7** Percentage of U.S. adults who support same-sex marriage, by generation. In surveys of nationally representative samples of several thousand Americans age 18 and older, support for allowing same-sex couples to marry legally increased from 2005 to 2015 among all generations. Younger cohorts are the most accepting; nearly three-fourths of Millennials approve of legalized same-sex marriage. (Based on Pew Research Center, 2010b, 2015f.)

THINKSTOCK/COMSTOCK IMAGES/GETTY IMAGES

Gay and lesbian romantic partners, like heterosexual partners, tend to be similar in education and background. With greater openness and political activism, attitudes toward same-sex relationships have become more accepting.

An estimated 3.8 percent of U.S. men and women—more than 8 million adults—identify as lesbian, gay, bisexual, or transgender, with women substantially more likely than men to report a bisexual orientation (Gallup, 2015a). But many sexual minority adults do not reveal their sexual orientation in survey research. This unwillingness to answer questions, engendered by a climate of discrimination, has limited researchers' access to information about the sex lives of gay men and lesbians.

The little evidence available indicates that relationships between same-sex partners follow the same patterns as other-sex relationships: People tend to seek out partners similar in education and background to themselves; partners in committed relationships have sex more often and are more satisfied; and the overall frequency of sex is generally moderate, though higher for gay than lesbian couples in early adulthood (Joyner, Manning, & Prince, 2015; Laumann et al., 1994). And in a survey of over 20,000 ethnically diverse men whose most recent sexual event involved a male partner, those who reported feeling love or affection rated sex as more pleasurable. Furthermore, expressions of love or affection for a partner, especially one's regular partner, were common among gay men of all ethnicities—African American, Asian, European American, and Hispanic (Calabrese et al., 2015). These findings challenge negative stereotypes of gay relationships, especially those of black men, as focused on sexual gratification without warmth and tenderness.

Sexual minorities tend to live in or near large cities, where many others share their sexual orientation, or in college towns, where attitudes are more accepting (Hubbard, Gorman-Murray, & Nash, 2015). Living in small communities where prejudice is intense and no social network exists through which to find compatible same-sex partners is isolating, lonely, and predictive of mental health problems (Swank, Frost, & Fahs, 2012). People who identify themselves as gay, lesbian, or bisexual also tend to

be well-educated (McGarrity, 2014). This probably reflects greater social and sexual liberalism among the more highly educated and therefore greater willingness to disclose a minority sexual orientation.

**Sexually Transmitted Infections.** In the United States, one in every four individuals is likely to contract a sexually transmitted infection (STI) at some point in life. Although the incidence is highest between ages 15 and 24 (see page 383 in Chapter 11), STIs continue to be prevalent throughout the twenties, when people accumulate most of their sexual partners yet often do not take appropriate measures to prevent disease transmission (Centers for Disease Control and Prevention, 2015b). Although both men and women are seriously affected, women are at greater risk for long-term health consequences. They are less likely to experience symptoms of the most common infections, which—left untreated—cause infertility and pregnancy complications.

HIV/AIDS remains a serious risk, with gay men bearing the greatest burden for this disease. Many have responded by changing their sexual practices—limiting number of sexual partners, choosing partners more carefully, and using condoms consistently and correctly. Heterosexuals at elevated risk due to a history of many partners have done the same, resulting in declines in HIV diagnoses in some subgroups. Still, the annual number of U.S. new HIV infections—about 50,000—has remained stable since the late 1990s (Centers for Disease Control and Prevention, 2015g). And the incidence of HIV-positive adults is higher in the United States than in any other industrialized nation (OECD, 2015d).

HIV largely spreads through men having sex with men and through heterosexual contact in poverty-stricken minority groups, among whom high rates of intravenous drug abuse coexist with poor health, inadequate education, high life stress, and hopelessness. People overwhelmed by these problems are least likely to take preventive measures. Among low-income African Americans and Hispanics, HIV diagnoses have risen by over 20 percent in the past decade (Centers for Disease Control and Prevention, 2016a).

Yet HIV/AIDS can be contained and reduced—through sex education extending from childhood into adulthood and through access to health services, condoms, and clean needles and syringes for high-risk individuals. In view of susceptibility among women, who account for one-fourth of cases in North America and Western Europe and more than half in developing countries, a special need exists for female-controlled preventive measures (Wiringa, Gondwe, & Haggerty, 2015). Drug-based vaginal gels and rings that kill or inactivate the virus have shown promising results and are undergoing further testing.

**Sexual Coercion.** To celebrate the end of final exams, Kelsey, a sophomore at a large university, went to a party at a friend's off-campus apartment, consumed alcohol, and lapsed into a stupor, fading in and out of consciousness. When she awoke, she found herself in a bedroom with another partyer—a male student—on top of her. Though she shouted “no” and tried to push him off, he used force. Then several more men

Cultural forces, including gender stereotyping and societal acceptance of violence, contribute to the high incidence of sexual coercion. Organizations like Take Back the Night aim to make communities safer by increasing awareness about sexual violence.

joined in (Krakauer, 2015). Hours later, Kelsey reported the attack, but the police suggested that because she was partially conscious, the sex might have been consensual.

An estimated 19 percent of U.S. women, sometime in their lives, have endured *rape*, legally defined as vaginal, anal, or oral penetration with a body part or object by force, by threat of harm, or when the victim is incapable of giving consent (because of alcohol consumption, mental illness, or intellectual disability). About 45 percent of women have experienced other forms of sexual coercion. The majority of victims (nearly 8 out of 10) were first victimized before age 25. The incidence is especially high on college campuses (Centers for Disease Control and Prevention, 2014d; Fedina, Holmes, & Backes, 2016). Like Kelsey, women are vulnerable to acquaintances and strangers, although in most instances their abusers are men they know well. Sexual coercion crosses SES and ethnic lines; people of all walks of life are offenders and victims.

Personal characteristics of perpetrators are far more dependable predictors of sexual coercion than those of victims. Men who commit these acts tend to be manipulative of others, lack empathy and remorse, pursue casual sexual relationships rather than emotional intimacy, approve of violence against women, and accept rape myths (such as “Women really want to be raped”). Perpetrators also interpret women’s social behaviors inaccurately, viewing friendliness as seductiveness, assertiveness as hostility, and resistance as desire (Abbey & Jacques-Tiura, 2011). Furthermore, sexual abuse in childhood, promiscuity in adolescence, and alcohol abuse in adulthood are associated with sexual coercion. Approximately half of all sexual assaults take place while people are intoxicated (Black, 2011).

## LOOK and LISTEN

Obtain from your campus student services or police department the number of sexual assaults reported during the most recent year. What percentage involved alcohol? What prevention and intervention services does your college offer?

Cultural forces also contribute. When men are taught from an early age to be dominant, competitive, and aggressive and women to be submissive and cooperative, the themes of rape are reinforced. Societal acceptance of violence also sets the stage for rape, which typically occurs in relationships in which other forms of aggression are commonplace. Exposure to sexually aggressive pornography and other media images, which portray women desiring and enjoying the assault, also promote sexual coercion by dulling sensitivity to its harmful consequences.

About 2 percent of U.S. men have been victims of rape, and 23 percent victims of other forms of sexual coercion. As with women, men under age 25 are at highest risk (Centers for Disease Control and Prevention, 2014d). Although rape victims report mostly male perpetrators, women are largely responsible for other forms of sexual coercion against men. Victimized men often say that women who committed these acts used threats of physical force or actual force, encouraged them to get drunk, or threatened to end the relationship unless they complied (French, Tilghman, & Malebranche, 2015). Social attitudes toward male victims are especially unsympathetic and blaming. Not surprisingly, few report these crimes.

**Consequences.** Women’s and men’s psychological reactions to rape resemble those of survivors of extreme trauma. Responses include shock, confusion, and symptoms of post-traumatic stress disorder (PTSD)—flashbacks, nightmares, irritability, psychological numbing, and difficulty concentrating—along with chronic fatigue, depression, substance abuse, social anxiety, difficulties with sexuality and intimacy, and suicidal thoughts (Gavey & Senn, 2014; Judson, Johnson, & Perez, 2013). Victims of ongoing sexual coercion may fall into a pattern of extreme passivity and fear of taking any action.

One-third to one-half of female rape victims are physically injured. From 4 to 30 percent contract STIs, and pregnancy results in about 5 percent of cases. Furthermore, victims of rape (and other sexual crimes) report more symptoms of illness across almost all body systems. And they are more likely to engage in negative health behaviors, including smoking and alcohol use (Black, 2011; Schewe, 2007).

**Prevention and Treatment.** Many female rape victims do not get help because fear over provoking another attack keeps them from confiding even in trusted family members and friends. A variety of community services, including safe houses, crisis hotlines, support groups, and legal assistance, exist to help women take refuge from abusive partners, but most are underfunded and cannot reach out to everyone in need. Practically no services are available for victimized men, who are often too embarrassed to come forward.

The trauma induced by rape is severe enough that therapy is vital—both individual treatment to reduce anxiety and depression and group sessions where contact with other survivors helps

## Applying what we Know

### Preventing Sexual Coercion

SUGGESTION	DESCRIPTION
Reduce gender stereotyping and gender inequalities.	The roots of men's sexual coercion of women lie in the historically subordinate status of women, which keeps women economically dependent on men and therefore poorly equipped to avoid partner violence. At the same time, increased public awareness that women commit sexually aggressive acts is needed.
Mandate treatment for both male and female perpetrators.	Ingredients of effective intervention include combating rape myths that victims "wanted it" and are to blame; inducing personal responsibility for coercive behavior; teaching social awareness, social skills, and anger management; and developing a support system to prevent future attacks.
Expand interventions for children and adolescents who have witnessed violence between their parents.	Although most child witnesses to parental violence do not become involved in abusive relationships as adults, they are at increased risk.
Teach both men and women to take precautions that lower the risk of sexual assault.	Risk of sexual assault can be reduced by communicating sexual limits clearly to a date; developing supportive ties to neighbors; increasing the safety of the immediate environment (for example, installing deadbolt locks, checking the back seat of the car before entering); avoiding deserted areas; not walking alone after dark; and leaving parties where alcohol use is high.
Broaden definitions of rape to be gender-neutral.	In a few U.S. states, where the definition of rape is limited to vaginal or anal penetration with a body part, a woman legally cannot rape a man. A universally applied definition that encompasses women as both victims and perpetrators is needed.

counter isolation and self-blame (Street, Bell, & Ready, 2011). Other critical features that foster recovery include

- *Routine screening for victimization* during health-care visits to ensure referral to community services and protection from future harm
- *Validation of the experience*, by acknowledging that many others have been similarly physically and sexually assaulted; that such assaults lead to a wide range of persisting symptoms, are illegal and inappropriate, and should not be tolerated; and that the trauma can be overcome
- *Safety planning*, even when the abuser is no longer present, to prevent recontact and reassault. This includes information about how to obtain police protection, legal intervention, a safe shelter, and other aid should a rape survivor be at risk again.

Finally, many steps can be taken at the level of the individual, the community, and society to prevent sexual coercion. Some are listed in Applying What We Know above.

## Psychological Stress

A final health concern, threaded throughout previous sections, has such a broad impact that it merits a comment of its own. Psychological stress, measured in terms of adverse social conditions, traumatic experiences, negative life events, or daily hassles, is related to a wide variety of unfavorable health outcomes—both unhealthy behaviors and clear physical consequences. Recall from earlier chapters that intense, persistent stress, from the prenatal period on, disrupts the brain's inherent ability to manage

stress, with long-term consequences. For individuals with childhood histories of stress, continuing stressful experiences combine with an impaired capacity to cope with stress, heightening the risk of adult health impairments.

As SES decreases, exposure to diverse stressors rises—an association that plays an important role in the strong connection between low SES and poor health (see pages 444–445). Chronic stress is linked to overweight and obesity, diabetes, hypertension, and atherosclerosis. And in susceptible individuals, acute stress can trigger cardiac events, including heartbeat rhythm abnormalities and heart attacks (Bekkouche et al., 2011; Kelly & Ismail, 2015). These relationships contribute to the high incidence of heart disease in low-income groups, especially African Americans. Compared with higher-SES individuals, low-SES adults show a stronger cardiovascular response to stress, perhaps because they more often perceive stressors as unsolvable (Carroll et al., 2007). Earlier we mentioned that stress interferes with immune system functioning, a link that may underlie its relationship to several forms of cancer. And by reducing digestive activity as blood flows to the brain, heart, and extremities, stress can cause gastrointestinal difficulties, including constipation, diarrhea, colitis, and ulcers (Donatelle, 2015).

The many challenging tasks of early adulthood make it a particularly stressful time of life. Young adults more often report depressive symptoms than middle-aged people, many of whom have attained vocational success and financial security and are enjoying more free time as parenting responsibilities decline (Nolen-Hoeksema & Aldao, 2011). Also, as we will see in Chapters 15 and 16, because of their longer life experience, middle-aged and older adults are better than young adults at coping with stress.

In previous chapters, we repeatedly noted the stress-buffering effect of social support, which continues throughout life. Helping young adults establish and maintain satisfying, caring social ties is as important a health intervention as any we have mentioned.

## Ask yourself

**CONNECT** Describe history-graded influences that have contributed to the obesity epidemic. (To review this aspect of the lifespan perspective, refer to pages 9–10 in Chapter 1.)

**APPLY** Tom had been going to a health club three days a week after work, but job pressures convinced him that he no longer had time for regular exercise. Explain to Tom why he should keep up his exercise regimen, and suggest ways to fit it into his busy life.

**REFLECT** Have you used online dating sites or dating apps? Do you know others who have used them? In your view, what are the strengths and limitations of Internet dating as a way to find a compatible romantic partner?

## COGNITIVE DEVELOPMENT

The cognitive changes of early adulthood are supported by further development of the cerebral cortex, especially the prefrontal cortex and its connections with other brain regions. Pruning of synapses along with growth and myelination of stimulated neural fibers continue, though at a slower pace than in adolescence. These changes result in continued fine-tuning of the *prefrontal cognitive-control network*, which achieves a better balance with the brain's *emotional/social network* as sensation seeking gradually diminishes (see pages 373–374 in Chapter 11). Consequently, planning, reasoning, and decision making improve, supported by major life events of this period—including attaining higher education, entering a career, and grappling with the demands of marriage and child rearing (Taber-Thomas & Perez-Edgar, 2016). Furthermore, fMRI evidence reveals that as young adults become increasingly proficient in a chosen field of endeavor, regions of the cerebral cortex specialized for those activities undergo further *experience-dependent brain growth* (see page 124 in Chapter 4). Besides more efficient functioning, structural changes occur as greater knowledge and refinement of skills result in more cortical tissue devoted to the task and, at times, reorganization of brain areas governing the activity (Lenroot & Giedd, 2006).

How does cognition change in early adulthood? Lifespan theorists have examined this question from three familiar vantage points. First, they have proposed transformations in the structure of thought—new, qualitatively distinct ways of thinking that extend the cognitive-developmental changes of adolescence. Second, adulthood is a time of acquiring advanced knowledge in a particular area, an accomplishment that has important implications for information processing and creativity. Finally, researchers are interested in the extent to which the diverse mental abilities assessed by intelligence tests remain stable or change during the adult years—a topic addressed in Chapter 15.

## Changes in the Structure of Thought

**13.7** Explain how thinking changes in early adulthood.

Sharese described her first year in graduate school as a “cognitive turning point.” As part of her internship in a public health clinic, she observed firsthand the many factors that affect human health-related behaviors. For a time, the realization that everyday dilemmas did not have clear-cut solutions made her intensely uncomfortable. “Working in this messy reality is so different from the problem solving I did in my undergraduate classes,” she told her mother over the phone one day.

Piaget (1967) recognized that important advances in thinking follow the attainment of formal operations. He observed that adolescents prefer an idealistic, internally consistent perspective on the world to one that is vague, contradictory, and adapted to particular circumstances (see Chapter 11, page 393). Sharese’s reflections fit the observations of researchers who have studied **postformal thought**—cognitive development beyond Piaget’s formal operational stage. To clarify how thinking is restructured in adulthood, let’s look at some influential theories, along with supportive research. Together, they show how personal effort and social experiences combine to spark increasingly rational, flexible, and practical ways of thinking that accept uncertainties and vary across situations.

## Epistemic Cognition

The work of William Perry (1981, 1970/1998) provided the starting point for an expanding research literature on the development of *epistemic cognition*. *Epistemic* means “of or about knowledge,” and **epistemic cognition** refers to our reflections on how we arrived at facts, beliefs, and ideas. When mature, rational thinkers reach conclusions that differ from those of others, they consider the justifiability of their conclusions. When they cannot justify their approach, they revise it, seeking a more balanced, adequate route to acquiring knowledge.

**Development of Epistemic Cognition.** Perry wondered why young adults respond in dramatically different ways to the diversity of ideas they encounter in college. To find out, he interviewed Harvard University undergraduates at the end of each of their four years, asking “what stood out” during the previous year. Responses indicated that students’ reflections on knowing changed as they experienced the complexities of university life and moved closer to adult roles—findings confirmed in many subsequent studies (King & Kitchener, 2002; Magolda, Abes, & Torres, 2009; Magolda et al., 2012).

Younger students regarded knowledge as made up of separate units (beliefs and propositions), whose truth could be determined by comparing them to objective standards—standards that exist apart from the thinking person and his or her situation. As a result, they engaged in **dualistic thinking**, dividing information, values, and authority into right and wrong, good and bad,

we and they. As one first-year college student put it, “When I went to my first lecture, what the man said was just like God’s word. I believe everything he said because he is a professor ... and this is a respected position” (Perry, 1981, p. 81). When asked, “If two people disagree on the interpretation of a poem, how would you decide which one is right?” a sophomore replied, “You’d have to ask the poet. It’s his poem” (Clinchy, 2002, p. 67). Dualistic thinkers approach learning by accepting what they are given.

Older students, in contrast, had moved toward **relativistic thinking**, viewing all knowledge as embedded in a framework of thought. Aware of a diversity of opinions on many topics, they gave up the possibility of absolute truth in favor of multiple truths, each relative to its context. As a result, their thinking became more flexible and tolerant. As one college senior put it, “Just seeing how [famous philosophers] fell short of an all-encompassing answer, [you realize] that ideas are really individualized. And you begin to have respect for how great their thought could be, without its being absolute” (Perry, 1970/1998, p. 90). Relativistic thinking leads to the realization that one’s own beliefs are often subjective because several frameworks may satisfy the criterion of internal logical consistency (Sinnott, 2003). Thus, the relativistic thinker is acutely aware that each person, in arriving at a position, creates her own “truth.”

Eventually, the most mature individuals progress to **commitment within relativistic thinking**. Instead of choosing between opposing views, they try to formulate a more personally satisfying perspective that synthesizes contradictions. When considering which of two theories studied in a college course is better or which of several movies most deserves an Oscar, the individual moves beyond the stance that everything is a matter of opinion and generates rational criteria against which options can be evaluated (Moshman, 2013). At the same time, mature thinkers willingly revise their internal belief system when presented with relevant evidence.

By the end of the college years, some students reach this extension of relativism. Adults who attain it generally display a more sophisticated approach to learning, in which they actively seek differing perspectives to deepen their knowledge and understanding and to clarify the basis for their own perspective. Notice how commitment within relativistic thinking involves the information-gathering cognitive style (see page 410 in Chapter 12) and pursuit of personally meaningful beliefs, values, and goals essential to healthy identity development. Mature epistemic cognition also contributes greatly to effective decision making and problem solving.

### Importance of Peer Interaction and Reflection.

Advances in epistemic cognition depend on further gains in metacognition, which are likely to occur in situations that challenge young people’s perspectives and induce them to consider the rationality of their thought processes (Barzilai & Zohar, 2015). In a study of the college learning experiences of seniors scoring low and high in epistemic cognition, high-scoring students frequently reported activities that encouraged them to struggle with realistic but ambiguous problems in a support-

WILL KIRK/HOMEWOODPHOTO/JHU.EDU

A team of university students participates in a global competition to design a more protective, lightweight, and comfortable suit for Ebola workers. Collaboratively tackling challenging, real-world problems leads to gains in epistemic cognition.

ive environment, in which faculty were committed to helping them understand how knowledge is constructed and why it must be subject to revision. For example, an engineering major, in describing an airplane-design project that required advanced epistemic cognition, mentioned his discovery that “you can design 30 different airplanes and each one’s going to have its benefits and there’s going to be problems with each one” (Marra & Palmer, 2004, p. 116). Low-scoring students rarely mentioned such experiences.

In tackling challenging, ill-structured problems, interaction among individuals who are roughly equal in knowledge and authority is beneficial because it prevents acceptance of another’s reasoning simply because of greater power or expertise. When college students were asked to devise the most effective solution to a difficult logical problem, only 3 out of 32 students (9 percent) in a “work-alone” condition succeeded. But in an “interactive” condition, 15 out of 20 small groups (75 percent) arrived at the best answer following extensive discussion (Moshman & Geil, 1998). Whereas few students working alone reflected on their solution strategies, most groups engaged in a process of “collective rationality” in which members challenged one another to justify their reasoning and collaborated in working out the most effective strategy.

Of course, reflection on one’s own thinking can also occur individually. But peer interaction fosters the necessary type of individual reflection: arguing with oneself over competing ideas and strategies and coordinating opposing perspectives into a new, more effective structure. As at earlier ages, peer collaboration remains a highly effective basis for education in early adulthood.

### LOOK and LISTEN

Describe learning experiences in one of your college courses that advanced your epistemic cognition. How did your thinking change?

Perry's theory and the research it stimulated are based on samples of highly educated young adults. These investigators acknowledge that progress in epistemic cognition is probably limited to people confronting the multiplicity of viewpoints typically encountered during a college education and that the most advanced attainment—commitment within relativism—often requires advanced graduate study (Greene, Torney-Purta, & Azevedo, 2010; King & Kitchener, 2002). But the underlying theme—thought less constrained by the need to find one answer to a question and more responsive to its context—is also evident in another theory of adult cognition.

## Pragmatic Thought and Cognitive-Affective Complexity

Gisella Labouvie-Vief's (1980, 1985) portrait of adult cognition echoes features of Perry's theory. Adolescents, she points out, operate within a world of possibility. Adulthood involves movement from hypothetical to **pragmatic thought**, a structural advance in which logic becomes a tool for solving real-world problems.

The need to specialize motivates this change. As adults select one path out of many alternatives, they become more aware of the constraints of everyday life. And in the course of balancing various roles, they accept contradictions as part of existence and develop ways of thinking that thrive on imperfection and compromise. Sharese's friend Christy, a married graduate student and parent of her first child at age 26, illustrates:

I've always been a feminist, and I wanted to remain true to my beliefs in family and career. But this is Gary's first year of teaching high school, and he's saddled with four preparations and coaching the school's basketball team. At least for now, I've had to settle for "give-and-take feminism"—going to school part-time and shouldering most of the child-care responsibilities while he gets used to his new job. Otherwise, we'd never make it financially.

Labouvie-Vief (2003, 2005, 2015) also points out that young adults' enhanced reflective capacities alter the dynamics of their emotional lives: They become more adept at integrating cognition with emotion and, in doing so, again make sense of discrepancies. Examining the self-descriptions of 10- to 80-year-olds diverse in SES, Labouvie-Vief found that from adolescence through middle adulthood, people gained in **cognitive-affective complexity**—awareness of conflicting positive and negative feelings and coordination of them into a complex, organized structure that recognizes the uniqueness of individual experiences (see Figure 13.8) (Labouvie-Vief, 2008; Labouvie-Vief et al., 2007). For example, one 34-year-old combined roles, traits, and diverse emotions into this coherent self-description: "With the recent birth of our first child, I find myself more fulfilled than ever, yet struggling in some ways. My elation is tempered by my gnawing concern over meeting all my responsibilities in a satisfying way while remaining an individualized person with needs and desires."

**FIGURE 13.8** Changes in cognitive-affective complexity from adolescence to late adulthood. Performance, based on responses of several hundred 10- to 80-year-olds' descriptions of their roles, traits, and emotions, increased steadily from adolescence through early adulthood, peaked in middle age, and fell off in late adulthood when (as we will see in later chapters) basic information-processing skills decline. (From G. Labouvie-Vief, 2003, "Dynamic Integration: Affect, Cognition, and the Self in Adulthood," *Current Directions in Psychological Science*, 12, p. 203, copyright © 2003, Sage Publications. Reprinted by permission of SAGE Publications.)

Cognitive-affective complexity promotes greater awareness of one's own and others' perspectives and motivations. As Labouvie-Vief notes, it is a vital aspect of adult *emotional intelligence* (see page 317 in Chapter 9) and is valuable in solving many pragmatic problems. Individuals high in cognitive-affective complexity view events and people in a tolerant, open-minded fashion. And because cognitive-affective complexity involves accepting and making sense of both positive and negative feelings, it helps people regulate intense emotion and, therefore, think rationally about real-world dilemmas, even those that are laden with negative information (Labouvie-Vief, Grünh, & Studer, 2010).

Awareness of multiple truths, integration of logic with reality, and cognitive-affective complexity sum up qualitative transformations in thinking under way in early adulthood. As we will see next, adults' increasingly specialized and context-bound thought, although it closes off certain options, opens new doors to higher levels of competence.

## Expertise and Creativity

### 13.8 What roles do expertise and creativity play in adult thought?

In Chapter 9, we noted that children's expanding knowledge improves their ability to remember new information related to what they already know. For young adults, **expertise**—acquisition of extensive knowledge in a field or endeavor—is supported

by the specialization that begins with selecting a college major or an occupation, since it takes many years to master any complex domain. Experts' curiosity, even passion, for their field fuels this sustained learning. As expertise is attained, it has a profound impact on information processing.

Compared with novices, experts remember and reason more quickly and effectively. The expert knows more domain-specific concepts and represents them in richer ways—at a deeper and more abstract level and as having more features that can be linked to other concepts. As a result, unlike novices, whose understanding is superficial, experts approach problems with underlying principles in mind. For example, a highly trained physicist notices when several problems deal with conservation of energy and can therefore be solved similarly. In contrast, a beginning physics student focuses only on surface features—whether the problem contains a disk, a pulley, or a coiled spring (Chi, 2006; Mayer, 2013). Experts can use what they know to arrive at many solutions automatically—through quick and easy remembering. And when a problem is challenging, they tend to plan ahead, systematically analyzing and categorizing elements and selecting the best from many possibilities, while the novice proceeds more by trial and error.

In addition to effective problem solving, expertise is necessary for creativity (Weissberg, 2006). The creative products of adulthood differ from those of childhood in that they are not just original but also directed at a social or aesthetic need. Mature creativity requires a unique cognitive capacity—the ability to formulate new, culturally meaningful problems and to ask significant questions that have not been posed before (Rostan, 1994). Movement from *problem solving* to *problem finding* is a core feature of postformal thought evident in highly creative artists and scientists.

Case studies support the 10-year rule in development of master-level creativity—a decade between initial exposure to a field and sufficient expertise to produce a creative work. Furthermore, a century of research reveals that creative productivity typically rises in early adulthood, peaks in the late thirties or early forties, and gradually declines, though creative individuals near the end of their careers are usually more productive than those just starting their careers (Simonton, 2012). But exceptions exist. Those who get an early start in creativity tend to peak and drop off sooner, whereas “late bloomers” reach their full stride at older ages. This suggests that creativity is more a function of “career age” than of chronological age.

The course of creativity also varies across disciplines and individuals (Simonton, 2012; Simonton & Damian, 2013). For example, poets, visual artists, and musicians typically show an early rise in creativity, perhaps because they do not need extensive formal education before they begin to produce. Academic scholars and scientists, who must earn higher academic degrees and spend years doing research to make worthwhile contributions, tend to display their achievements later and over a longer time. And whereas some creators are highly productive, others make only a single lifetime contribution.

Though creativity is rooted in expertise, not all experts are creative. Creativity also requires other qualities. A vital ingredient is the capacity to “think intuitively” with a reduced filter—to avoid dismissing information that, at first glance, appears irrelevant. Although this lessened inhibition is a liability in other forms of cognition, it contributes to creators' capacity to think “outside the box”—to come up with numerous, unusual associations that they can capitalize on during the creative process (Carson, Peterson, & Higgins, 2003; Dane et al., 2011).

In personality, creative individuals are tolerant of ambiguity, open to new experiences, persistent and driven to succeed, capable of deep task involvement, and willing to try again after failure (Zhang & Sternberg, 2011). Finally, creativity demands time and energy. For women especially, it may be postponed or disrupted by child rearing, divorce, or an unsupportive partner.

In sum, creativity is multiply determined. When personal and situational factors jointly promote it, creativity can continue for many decades, well into old age.

## Ask yourself

**CONNECT** Why is expertise necessary for creativity? What additional ingredients are essential for creative thought?

**APPLY** For her lifespan development course, Marcia wrote a paper discussing the differing implications of Piaget's and Vygotsky's theories for education. Next, she reasoned that combining the two perspectives is more effective than relying on either position by itself. Explain how Marcia's reasoning illustrates advanced epistemic cognition.

**REFLECT** Describe a classroom experience or assignment in one of your college courses that promoted relativistic thinking.

© MICHAEL J. DOOLITTLE/THE IMAGE WORKS

Visual artists as well as poets and musicians typically show an early rise in creativity, though they may need a decade or more to produce master-level creative works.

## The College Experience

**13.9** Describe the impact of a college education on young people's lives, and discuss the problem of dropping out.

Looking back at the trajectory of their lives, many people view the college years as formative—more influential than any other period of adulthood. This is not surprising. College serves as a “developmental testing ground,” a time for devoting full attention to exploring alternative values, roles, and behaviors. To facilitate this exploration, college exposes students to a form of “culture shock”—encounters with new ideas and beliefs, new freedoms and opportunities, and new academic and social demands.

Nearly 70 percent of U.S. recent high school graduates enrolled in an institution of higher education. Among college students, 60 percent followed this traditional route of starting college shortly after finishing high school, earning their undergraduate degree by age 24. The remaining 40 percent, who range widely in age, delayed college entry because of financial constraints, family responsibilities, or other life circumstances (U.S. Department of Education, 2015). Most research on the transforming impact of attending college focuses on traditional students between ages 18 and 24. We will consider nontraditional students in Chapter 15.

### Psychological Impact of Attending College

Thousands of studies reveal broad psychological changes from the freshman to the senior year of college (Montgomery & Côté, 2003; Pascarella & Terenzini, 1991, 2005). As research on episodic cognition revealed, students become better at reasoning about problems that have no clear solution, identifying the strengths and weaknesses of opposing sides of complex issues, and reflecting on the quality of their thinking. Their attitudes and values also broaden. They show increased interest in literature, the performing arts, and philosophical and historical issues and greater tolerance for racial and ethnic diversity. Also, as noted in Chapter 12, college leaves its mark on moral reasoning by fostering concern with individual rights and human welfare, sometimes expressed in political activism. Finally, exposure to multiple worldviews encourages young people to look more closely at themselves. During the college years, students develop greater self-understanding, enhanced self-esteem, and a firmer sense of identity.

How do these interrelated changes come about? The impact of college is jointly influenced by the richness of campus academic and out-of-class offerings and students' engagement in those experiences. The more students study and interact with both faculty and diverse peers in academic and extracurricular settings, the more they benefit cognitively—in grasping the complex causes of events, thinking critically, and generating effective problem solutions (Bowman, 2011a). Also, interacting with racially and ethnically mixed peers—both in courses exploring

© ST. PETERSBURG TIMES/BRENDAN FITTERER/THE IMAGE WORKS

Community college students join in a Peace Week activity, keeping pace with the beat of a drum circle. The more students interact with diverse peers in academic and extracurricular settings, the more they benefit cognitively from attending college.

diversity issues and in out-of-class settings—predicts gains in civic engagement. And students who connect their community service experiences with their classroom learning show large cognitive gains (Bowman, 2011b; Parker & Pascarella, 2013). These findings underscore the importance of programs that integrate commuting students into extracurricular campus life.

To what extent are U.S. college students sufficiently engaged in educationally meaningful experiences to transition successfully to the labor market? For research that bears on this question, refer to the Social Issues: Education box on the following page.

### Dropping Out

In the 1970s, the United States ranked first in the world in percentage of young adults with college degrees; today it is twelfth, with just 44 percent of 25- to 34-year-olds having graduated. It lags far behind such countries as Canada, Japan, and South Korea, the global leader—where the rate is 66 percent (OECD, 2014). Major contributing factors are the high U.S. child poverty rate; poor-quality schools in low-income neighborhoods; and high rates of high school dropout among economically disadvantaged, ethnic minority teenagers (see page 402 in Chapter 11). College leaving is also influential: Six years after enrolling at a four-year institution, 42 percent of U.S. students have not earned their degrees. Most dropouts leave within the first year and many within the first six weeks. Dropout rates are higher in colleges with less selective admission requirements (U.S. Department of Education, 2015). And ethnic minority students from low-SES families are, once again, at increased risk of dropping out.

Both personal and institutional factors contribute to college leaving. Most entering freshmen have high hopes for college life but find the transition difficult. Those who have trouble adapting—because of lack of motivation, poor study skills, financial pressures, or emotional dependence on parents—quickly develop negative attitudes toward the college environment. Often these exit-prone students do not meet with their

## Social Issues: Education

### How Important Is Academic Engagement in College for Successful Transition to the Labor Market?

**D**o critical thinking, complex reasoning, and written communication—skills designated by educators and employers as crucial for success in the twenty-first century economy—really matter in college graduates' efforts to secure a satisfying, well-paid job? To find out, researchers gave 1,600 students at 25 U.S. four-year colleges and universities a test of general collegiate learning in the fall of their first year and, again, around the time they graduated (Arum & Roksa, 2014). The students also responded to surveys and in-depth interviews about the meaningfulness of their college experiences. Two years after graduation, they reported on employment outcomes.

Participants' post-college paths varied widely. Some transitioned successfully to challenging work roles that launched them on a career track. But more than half were underemployed (in jobs not requiring a college education) or unemployed. Across institutions varying widely in admission requirements, senior-year collegiate learning scores predicted success at securing jobs requiring bachelor's level skills, along with student reports that their work was both cognitively challenging and personally fulfilling.

Successful graduates were keenly aware of this link between collegiate learning and post-college success. Ashley, who landed a well-paid job as a program coordinator at a senior center, commented that her college in-class

and out-of-class experiences taught her how “to work in groups, ... to think critically and be able to solve problems [and] to understand different perspectives” (Arum & Roksa, 2014, p. 77). In contrast, students with low collegiate learning scores found it hard to articulate the benefits of their college experiences. After an unsuccessful search for work related to his business degree, Nathan accepted a low-wage job as a delivery driver for a retail chain. Although he graduated with a high grade point average, he mentioned going to lots of parties, could think of little that stood out about his courses, and did not participate in any educationally relevant extracurricular activities.

Like Nathan, most participants gained little in collegiate learning during their four years of college. Since the 1970s, the time U.S. college students spend studying has declined by half, while the time they devote to socializing and other forms of entertainment has risen dramatically (Brint & Cantwell, 2010). As institutions redefined students as consumers, academic demands receded and grade inflation increased.

Surveys of employers indicate that less than one-fourth of U.S. college graduates enter the labor market with excellent collegiate skills (Fischer, 2013). Clear evidence that critical thinking, complex reasoning, and written communication have substantial labor market payoffs underscores the need

Students who find their coursework both cognitively challenging and personally fulfilling are more likely to experience success in their post-college careers.

for colleges to promote students' involvement in academics and career-relevant extracurricular experiences, and to upgrade the rigor of their courses.

advisers or professors (Stewart, Lim, & Kim, 2015). At the same time, colleges that do little to help high-risk students, through developmental courses and other support services, have a higher percentage of dropouts.

Beginning to prepare young people in early adolescence with the necessary visions and skills can do much to improve college success. In a study that tracked nearly 700 young people from sixth grade until two years after high school graduation, a set of factors—grade point average, academic self-concept, persistence in the face of challenge, and parental SES and valuing of a college education—predicted college enrollment at age 20 (Eccles, Vida, & Barber, 2004). Although parental SES is difficult to modify, improving parents' attitudes and behaviors and students' academic motivation and educational aspirations is

within reach, through a wide array of strategies considered in Chapters 11 and 12.

Once young people enroll in college, reaching out to them, especially during the early weeks and throughout the first year, is crucial. Programs that forge bonds between teachers and students and that generously fund student services—providing academic support, counseling to address academic and personal challenges, part-time work opportunities, and meaningful extracurricular roles—increase retention. Membership in campus-based social and religious organizations is especially helpful in strengthening minority students' sense of belonging (Chen, 2012; Kuh, Cruce, & Shoup, 2008). Students who feel that their college community is concerned about them as individuals are far more likely to graduate.

## Vocational Choice

**13.10** Trace the development of vocational choice, and cite factors that influence it.

**13.11** What problems do U.S. non-college-bound young people face in preparing for a vocation?

Young adults, college-bound or not, face a major life decision: the choice of a suitable work role. Being a productive worker calls for many of the same qualities as being an active citizen and a nurturant family member—good judgment, responsibility, dedication, and cooperation. What influences young people’s decisions about careers? What is the transition from school to work like, and what factors make it easy or difficult?

### Selecting a Vocation

In societies with an abundance of career possibilities, occupational choice is a gradual process that begins long before adolescence and often extends into the mid-twenties. Major theorists view the young person as moving through several periods of vocational development (Gottfredson, 2005; Super, 1994):

- 1. The fantasy period:** In early and middle childhood, children gain insight into career options by fantasizing about them (Howard & Walsh, 2010). Their preferences, guided largely by familiarity, glamour, and excitement, bear little relation to the decisions they will eventually make.
- 2. The tentative period:** Between ages 11 and 16, adolescents think about careers in more complex ways, at first in terms of their *interests*, and soon—as they become more aware of personal and educational requirements for different vocations—in terms of their *abilities* and *values*. “I like science and the process of discovery,” Sharese thought as she neared high school graduation. “But I’m also good with people, and I’d like to do something to help others. So maybe teaching or medicine would suit my needs.”
- 3. The realistic period:** By the late teens and early twenties, with the economic and practical realities of adulthood just around the corner, young people start to narrow their options. A first step is often further *exploration*—gathering more information about possibilities that blend with their personal characteristics. In the final phase, *crystallization*, they focus on a general vocational category and experiment for a time before settling on a single occupation (Stringer, Kerpelman, & Skorikov, 2011). As a college sophomore, Sharese pursued her interest in science, but she had not yet selected a major. Once she decided on chemistry, she considered whether to pursue teaching, medicine, or public health.

### Factors Influencing Vocational Choice

Most, but not all, young people follow this pattern of vocational development. A few know from an early age just what they want to be and follow a direct path to a career goal. Some decide and

later change their minds, and still others remain undecided for an extended period. College students are granted added time to explore various options. In contrast, the life conditions of many low-SES youths restrict their range of choices.

Making an occupational choice is not simply a rational process in which young people weigh abilities, interests, and values against career options. Like other developmental milestones, it is the result of a dynamic interaction between person and environment (Sharf, 2013). A great many influences feed into the decision, including personality, family, teachers, and gender stereotypes, among others.

**Personality.** People are attracted to occupations that complement their personalities. John Holland (1985, 1997) identified six personality types that affect vocational choice:

- The *investigative person*, who enjoys working with ideas, is likely to select a scientific occupation (for example, anthropologist, physicist, or engineer).
- The *social person*, who likes interacting with people, gravitates toward human services (counseling, social work, or teaching).
- The *realistic person*, who prefers real-world problems and working with objects, tends to choose a mechanical occupation (construction, plumbing, or surveying).
- The *artistic person*, who is emotional and high in need for individual expression, looks toward an artistic field (writing, music, or the visual arts).
- The *conventional person*, who likes well-structured tasks and values material possessions and social status, has traits well-suited to certain business fields (accounting, banking, or quality control).
- The *enterprising person*, who is adventurous, persuasive, and a strong leader, is drawn to sales and supervisory positions or to politics.

© DANNY MOLOSHOK/NEWSCAST/THE IMAGE WORKS

Young architects work on their award-winning model that shows how Los Angeles might look in the year 2106. Vocational choice is moderately influenced by personality, with external factors such as parenting, education, job opportunities, and life circumstances all playing important roles.

Research confirms a relationship between personality and vocational choice in diverse cultures, but it is only moderate (Spokane & Cruza-Guet, 2005; Tang, 2009). Many people are blends of several personality types and can do well at more than one kind of occupation.

Furthermore, career decisions are made in the context of family influences, financial resources, educational and job opportunities, and current life circumstances. For example, Sharese's friend Christy scored high on Holland's investigative dimension. But after she married, had her first child, and faced increasing financial pressures, she postponed her dream of becoming a college professor and chose a human services career that required fewer years of education and offered reasonable likelihood of employment after graduation. Thus, personality takes us only partway in understanding vocational choice.

**Family Influences.** Young people's vocational aspirations correlate strongly with their parents' jobs. Individuals who grew up in higher-SES homes are more likely to select high-status, white-collar occupations, such as doctor, lawyer, scientist, or engineer. In contrast, those with lower-SES backgrounds tend to choose less prestigious, blue-collar careers—for example, plumber, construction worker, food service employee, or office worker. Parent-child vocational similarity is partly a function of similarity in personality, intellectual abilities, and—especially—educational attainment (Ellis & Bonin, 2003; Schoon & Parsons, 2002). Number of years of schooling completed is a powerful predictor of occupational status.

Other factors also promote family resemblance in occupational choice. Higher-SES parents are more likely to give their children important information about the worlds of education and work and to have connections with people who can help the young person obtain a high-status position (Kalil, Levine, & Ziol-Guest, 2005; Levine & Sutherland, 2013). In a study of African-American mothers' influence on their daughters' academic and career goals, college-educated mothers engaged in a wider range of strategies to promote their daughters' progress, including gathering information on colleges and areas of study and identifying knowledgeable professionals who could help (Kerpelman, Shoffner, & Ross-Griffin, 2002).

Parenting practices also shape work-related preferences. Recall from Chapter 2 that higher-SES parents tend to promote curiosity and self-direction, which are required in many high-status careers. Still, all parents can foster higher aspirations. Parental guidance, pressure to do well in school, college-going expectations, and encouragement toward high-status occupations predict confidence in career choice and educational and career attainment beyond SES (Bryant, Zvonkovic, & Reynolds, 2006; Gregory & Huang, 2013; Stringer & Kerpelman, 2010).

**Teachers.** Young adults preparing for or engaged in careers that require extensive education often report that teachers influenced their educational aspirations and career choice. High school students who say that most of their teachers are caring and accessible, interested in their future, and demand that they work hard feel more confident about choosing a personally suitable

career and succeeding at it (Metheny, McWhirter, & O'Neil, 2008). And in longitudinal research, teacher expectations for educational attainment predicted students' enrollment in college two years after high school graduation more strongly than did parents' expectations (Gregory & Huang, 2013; Sciarra & Ambrosina, 2011). Teacher expectations mattered most for low-SES students.

These findings provide yet another reason to promote positive teacher-student relations, especially for high school students from low-SES families. Teachers who offer encouragement and communicate with students about their potential can serve as an important source of resilience for these young people.

**Gender Stereotypes.** Over the past four decades, young women have expressed increasing interest in nontraditional occupations (Gati & Perez, 2014; Gottfredson, 2005). Changes in gender-role attitudes, along with a dramatic rise in numbers of employed mothers who serve as career-oriented models for their daughters, are common explanations for women's attraction to nontraditional careers.

But women's progress in entering and excelling at male-dominated professions has been slow. As Table 13.2 shows, although the percentage of women architects, engineers, lawyers, doctors, and business executives has risen in the United States over the past three decades, it still falls far short of equal representation. Women remain concentrated in less-well-paid, traditionally feminine professions such as social work, education,

**TABLE 13.2**  
**Percentage of Women in Various Professions**  
**in the United States, 1983 and 2015**

PROFESSION	1983	2015
Architect or engineer	5.8	15.1
Lawyer	15.8	34.5
Physician	15.8	37.9
Business executive	32.4	39.2 <sup>a</sup>
Author, artist, entertainer	42.7	47.6
Social worker	64.3	83.8
Elementary or middle school teacher	93.5	80.7
Secondary school teacher	62.2	59.2
College or university professor	36.3	46.5
Librarian	84.4	83.0
Registered nurse	95.8	89.4
Psychologist	57.1	70.3

Source: U.S. Department of Labor, 2016a.

<sup>a</sup>This percentage includes executives and managers at all levels. As of 2016, women made up only 4 percent of chief executive officers at Fortune 500 companies, although that figure represents twice as many as 10 years ago.

## Cultural Influences

### Masculinity at Work: Men Who Choose Nontraditional Careers

Ross had always planned to major in engineering, but in his sophomore year of college, he startled his family and friends by deciding to pursue a nursing degree instead. “I’ve never looked back,” Ross said. “I love the work.” He noted some benefits of being a male in a female work world, including rapid advancement and the high regard of women colleagues. “But as soon as they learn what I do,” Ross remarked with disappointment, “guys on the outside question my abilities and masculinity.”

What factors influence the slowly increasing number of men who, like Ross, enter careers dominated by women? Compared to their traditional-career counterparts, these men tend to be more liberal in their social attitudes, less gender-typed, less focused on the social status of their work, and more interested in working with people (Dodson & Borders, 2006; Jome, Surething, & Taylor, 2005). Perhaps their gender-stereotype flexibility allows them to choose occupations they find satisfying, even if those jobs are not typically regarded as appropriate for men. However, they do take into account the probable financial returns of their choice (Hardie, 2015). They orient more toward nontraditional careers with higher average incomes.

Interviews with male nurses, flight attendants, primary school teachers, and librarians confirm Ross’s observations: In line with stereotypes of men’s greater desire for promotion and leadership, co-workers tend to assume

they are more knowledgeable than they actually are. These men often report being offered choice job placements and opportunities to move quickly into supervisory positions, although many did not seek such advancement (Simpson, 2004; Williams, 2013). As one teacher commented, “I just want to be a good classroom teacher. What’s wrong with that?”

But when asked to reflect on how others reacted to their choice, many men express anxiety about being stigmatized—mostly by other men. To reduce these feelings, they frequently describe their job in ways that minimize its feminine image. For example, several librarians emphasized technical requirements by referring to their title as “information scientist” or “researcher.” Nurses sometimes distance themselves from a feminine work identity by specializing in “adrenaline-charged” areas such as accident or emergency (Simpson, 2005). Despite these tensions, as with Ross, a high level of private comfort with their career choice seems to prevail over uneasiness about the feminine public image of their work.

Still, men face certain barriers that resemble those of women preparing for nontraditional careers. For example, male students in college nursing programs often mention lack of male mentors and a “cooler” educational climate, which they attribute to implicit gender discrimination and unsupportive behaviors of women nurse educators (Meadus & Twomey, 2011). And many encounter the view

© ELIZABETH CREWS/THE IMAGE WORKS

This elementary school teacher is among the increasing number of men entering careers dominated by women. Compared with his traditional-career counterparts, he is likely to be less gender-typed and more interested in working with people.

that they are less able than women to perform stereotypically “feminine” aspects of their jobs, such as those requiring sensitivity and caring—experiences that can increase work-related stress (Sobiraj et al., 2015). These findings reveal that to facilitate entry into nontraditional careers, men, too, would benefit from supportive relationships with same-gender role models and an end to gender-biased beliefs and behaviors.

librarianship, and nursing (U.S. Department of Labor, 2016a). In virtually all fields, women’s achievements lag behind those of men, who write more books, make more discoveries, hold more positions of leadership, and produce more works of art.

Ability cannot account for these dramatic sex differences. Recall from Chapter 11 that girls are advantaged in reading and writing achievement, and the gender gap favoring boys in math is small and has been shrinking. Rather, gender-stereotyped messages play a key role. Although girls earn higher grades than boys, they reach secondary school less confident of their abilities, more likely to underestimate their achievement, and less likely to express interest in STEM careers (see page 395).

In college, the career aspirations of many women decline further as they question their capacity and opportunities to succeed in male-dominated fields and worry about combining a highly demanding career with family responsibilities (Chhin, Bleeker, & Jacobs, 2008; Sadler et al., 2012). Many college women talented in math and science settle on nonscience majors or non-STEM fields. An investigation of science-oriented young people in 50 nations revealed uniform findings: In every country, female students preferred careers in biology, agriculture, medicine, or another health profession, whereas male students favored computing, engineering, or math. And almost without exception, males expressed greater confidence in their science ability—

a gender difference that was considerably larger in industrialized than developing nations (Sikora & Pokropek, 2012). In economically advanced countries, the researchers speculated, gender-typed beliefs about science ability had far greater opportunity to become deeply ingrained and widespread.

These findings reveal a pressing need for programs that sensitize educators to the special problems women face in developing and maintaining high vocational aspirations and selecting nontraditional careers. Young women's aspirations rise in response to career guidance that encourages them to set goals that match their abilities and faculty who take steps to enhance their experiences in math and science courses. Contact with women scientists and engineers adds to female students' interest in and expectancies for success in STEM fields (Holdren & Lander, 2012). And such mentoring may help them see how altruistic values—which are particularly important to females—can be fulfilled within STEM occupations.

Compared to women, men have changed little in their interest in nontraditional occupations. See the Cultural Issues box on the previous page for research on the motivations and experiences of men who do choose female-dominated careers.

## Vocational Preparation of Non-College-Bound Young Adults

Sharese's younger brother Leon graduated from high school in a vocational track. Like approximately one-third of U.S. young people with a high school diploma, he had no current plans to go to college. While in school, Leon held a part-time job selling candy at the local shopping mall. He hoped to work in data processing after graduation, but six months later he was still a part-time sales clerk at the candy store. Although Leon had filled out many job applications, he got no interviews or offers.

Leon's inability to find a job other than the one he held as a student is typical for U.S. non-college-bound high school graduates. Although they are more likely to find employment than youths who drop out, they have fewer work opportunities than high school graduates of several decades ago. Nearly 20 percent of U.S. recent high school graduates who do not continue their education are unemployed (U.S. Department of Labor, 2015a). When they do find work, most hold low-paid, unskilled jobs. In addition, they have few alternatives for vocational counseling and job placement as they transition from school to work.

American employers regard recent high school graduates as unprepared for skilled business and industrial occupations and manual trades. And there is some truth to this impression. As noted in Chapter 11, unlike European nations, the United States has no widespread training system for non-college-bound youths. As a result, most graduate without work-related skills.

In Germany, young people who do not go to a *Gymnasium* (college-preparatory high school) have access to one of the most successful work-study apprenticeship systems in the world for entering business and industry. About 60 percent of German youths participate. After completing full-time schooling at age 15 or 16, they spend the remaining two years of compulsory

education in the *Berufsschule*, combining part-time vocational courses with an apprenticeship that is jointly planned by educators and employers. Students train in work settings for more than 300 blue- and white-collar occupations. Apprentices who complete the program and pass a qualifying examination are certified as skilled workers and earn union-set wages. Businesses provide financial support because they know that the program guarantees a competent, dedicated work force. Many apprentices are hired into well-paid jobs by the firms that train them (Audretsch & Lehmann, 2016). Because of the apprenticeship system, Germany has the lowest unemployment rate among 18- to 25-year-olds in Europe—less than 8 percent.

The success of the German system—and of similar systems in Austria, Denmark, Switzerland, and several East European countries—suggests that a national apprenticeship program would improve the transition from high school to work for U.S. young people. The many benefits of bringing together the worlds of schooling and work include helping non-college-bound young people establish productive lives right after graduation, motivating at-risk youths to stay in school, and contributing to the nation's economic growth. Nevertheless, implementing an apprenticeship system poses major challenges: overcoming the reluctance of employers to assume part of the responsibility for vocational training, ensuring cooperation between schools and businesses, and preventing low-SES youths from being concentrated in the lowest-skilled apprenticeship placements or from being unable to find any placement, an obstacle that Germany itself has not yet fully overcome (Lang, 2010). Currently, small-scale school-to-work projects in the United States are attempting to solve these problems and build bridges between learning and working.

Although vocational development is a lifelong process, adolescence and early adulthood are crucial periods for defining occupational goals and launching a career. Young people who are well-prepared for an economically and personally satisfying work life are much more likely to become productive citizens, devoted family members, and contented adults. The support of families, schools, businesses, communities, and society as a whole can contribute greatly to a positive outcome. In Chapter 14, we will take up the challenges of establishing a career and integrating it with other life tasks.

## Ask yourself

**CONNECT** What have you learned in previous chapters about development of gender stereotypes that helps explain women's slow progress in entering and excelling at male-dominated professions? (*Hint:* See Chapter 10, page 338, and Chapter 11, page 395.)

**APPLY** Diane, a first-year college student, knows that she wants to "work with people" but doesn't yet have a specific career in mind. Her father is a chemistry professor, her mother a social worker. What can Diane's parents do to broaden her awareness of the world of work and help her focus on an occupational goal?

**REFLECT** Describe personal and environmental influences on your progress in choosing a vocation.

## Summary / chapter 13

### PHYSICAL DEVELOPMENT

#### Biological Aging Is Under Way in Early Adulthood (p. 438)

##### 13.1 Describe current theories of biological aging, both at the level of DNA and body cells and at the level of tissues and organs.

- Once body structures reach maximum capacity and efficiency in the teens and twenties, **biological aging**, or **senescence**, begins.

© WOODWARD/ALAMY

- The programmed effects of specific genes may control certain age-related biological changes. For example, **telomere** shortening results in senescent cells, which contribute to disease and loss of function.
- DNA may also be damaged as random mutations accumulate, leading to less efficient cell repair and replacement and to abnormal cancerous cells. Release of **free radicals**, once thought to be a major contributor to age-related DNA and cellular damage, may instead activate DNA repair systems within cells, thereby lengthening life.
- The **cross-linkage theory of aging** suggests that over time, protein fibers form links and become less elastic, producing negative changes in many organs. Declines in the endocrine and immune systems may also contribute to aging.

#### Physical Changes (p. 440)

##### 13.2 Describe the physical changes of aging, paying special attention to the cardiovascular and respiratory systems, motor performance, the immune system, and reproductive capacity.

- Gradual physical changes take place in early adulthood and later accelerate. Declines in heart and lung performance are evident during exercise. Heart disease is a leading cause of death in adults, although it has decreased since the mid-twentieth century due to lifestyle changes and medical advances.

- Athletic skills requiring speed, strength, and gross-motor coordination peak in the early twenties; those requiring endurance, arm–hand steadiness, and aiming peak in the late twenties and early thirties. Inactivity rather than biological aging is largely responsible for age-related declines in motor performance.
- The immune response declines after age 20 because of shrinkage of the thymus gland and increased difficulty coping with physical and psychological stress.
- Women's reproductive capacity declines with age due to reduced quality and quantity of ova. In men, semen volume and sperm motility decrease gradually after age 35, and the percentage of abnormal sperm rises.

#### Health and Fitness (p. 444)

##### 13.3 Describe the influence of SES, nutrition, and exercise on health, and discuss obesity in adulthood.

- Health inequalities associated with SES increase in adulthood. Health-related circumstances and habits underlie these disparities.
- Sedentary lifestyles and diets high in sugar and fat have contributed to the U.S. overweight and obesity epidemic. Excess weight is associated with serious health problems, social discrimination, and early death.
- Some weight gain in adulthood reflects a decrease in **basal metabolic rate (BMR)**, but many young adults add excess weight. Effective treatment includes a nutritious diet low in calories plus regular exercise, recording of food intake and body weight, social support, and teaching problem-solving skills.
- Regular exercise reduces body fat, builds muscle, fosters resistance to disease, and enhances cognitive functioning and psychological well-being.

HERO IMAGES INC./ALAMY

##### 13.4 What are the most commonly abused substances, and what health risks do they pose?

- Tobacco, marijuana, and alcohol are the most commonly abused substances. Cigarette smokers, most of whom began before age 21, are at increased risk for many health problems, including decline in bone mass, heart attack, stroke, and numerous cancers.
- About one-third of heavy drinkers suffer from alcoholism, to which both heredity and environment contribute. Alcohol is implicated in liver and cardiovascular disease, certain cancers and other physical disorders, motor vehicle fatalities, crime, and sexual coercion.

##### 13.5 Describe sexual attitudes and behavior of young adults, and discuss sexually transmitted infections and sexual coercion.

- Most adults are less sexually active than media images suggest, but they display a wider range of sexual choices and lifestyles and have had more sexual partners than earlier generations. The Internet has become a popular way to initiate relationships.
- Adults in committed relationships report high satisfaction with their sex lives. Only a minority report persistent sexual problems—difficulties linked to biological factors and to low SES and psychological stress.

THINKSTOCK/COMSTOCK IMAGES/GETTY IMAGES

- Attitudes toward same-sex couples have become more accepting. Same-sex partners, like heterosexual partners, tend to be similar in education and background and more satisfied in committed relationships.
- Sexually transmitted infections (STIs) continue to be prevalent throughout the twenties; women are at great risk for lasting health consequences. AIDS, the most deadly STI, is spreading most rapidly through men having sex with men and through heterosexual contact in poverty-stricken minority groups.

- Most rape victims are women under age 25 who have been harmed by men they know well. Personal characteristics of perpetrators and cultural acceptance of strong gender typing and of violence contribute to sexual coercion. Although less often reported and recognized by authorities, men are also victims. Regardless of gender, rape survivors experience extreme trauma.

### 13.6 How does psychological stress affect health?

- Chronic psychological stress induces physical responses that contribute to cardiovascular disease, several types of cancer, and gastrointestinal problems. The challenges of early adulthood increase stress; young people can reduce stress by forming supportive social ties.

## COGNITIVE DEVELOPMENT

### Changes in the Structure of Thought (p. 456)

#### 13.7 Explain how thinking changes in early adulthood.

- Development of the cerebral cortex in early adulthood results in continued fine-tuning of the prefrontal cognitive-control network, which achieves a better balance with the brain's emotional/social network, contributing to improvements in planning, reasoning, and decision making.
- Cognitive development beyond Piaget's formal operations is known as **postformal thought**. In early adulthood, personal effort and social experiences combine to spark increasingly rational, flexible, and practical ways of thinking.
- In Perry's theory of **epistemic cognition**, college students move from **dualistic thinking**, dividing information into right and wrong, to **relativistic thinking**, awareness of multiple truths. The most mature individuals progress to **commitment within relativistic thinking**, which synthesizes contradictions.
- Advances in epistemic cognition depend on gains in metacognition. Peer collaboration on challenging, ill-structured problems is especially beneficial.

- In Labouvie-Vief's theory, the need to specialize motivates adults to move from hypothetical to **pragmatic thought**, which uses logic as a tool for solving real-world problems and accepts contradiction, imperfection, and compromise. Adults' enhanced reflective capacities permit gains in **cognitive-affective complexity**—coordination of positive and negative feelings into a complex, organized structure.

### Expertise and Creativity (p. 458)

#### 13.8 What roles do expertise and creativity play in adult thought?

- Specialization in college and in an occupation leads to **expertise**, which is necessary for both problem solving and creativity. Although creativity tends to rise in early adulthood and to peak in the late thirties or early forties, its development varies across disciplines and individuals. Diverse personal and situational factors jointly promote creativity.

© MICHAEL J. DOOLITTLE/THE IMAGE WORKS

### The College Experience (p. 460)

#### 13.9 Describe the impact of a college education on young people's lives, and discuss the problem of dropping out.

- College students' explorations, both academic and nonacademic, yield gains in knowledge and reasoning ability, broadening of attitudes and values, enhanced self-understanding and self-esteem, and a firmer sense of identity.
- Personal and institutional factors contribute to college dropout, which is more common in less selective colleges and among ethnic minority students from low-SES families. High-risk students benefit from interventions that show concern for them as individuals.

### Vocational Choice (p. 462)

#### 13.10 Trace the development of vocational choice, and cite factors that influence it.

- Vocational choice moves through a **fantasy period**, in which children explore career options by fantasizing about them; a **tentative period**, in which teenagers evaluate careers in terms of their interests, abilities, and values; and a **realistic period**, in which young people settle on a vocational category and then a specific occupation.

© ELIZABETH CREWS/THE IMAGE WORKS

- Vocational choice is influenced by personality; parents' provision of educational opportunities, vocational information, and encouragement; and close relationships with teachers who hold high educational expectations.
- Women's progress in male-dominated professions has been slow, and their achievements lag behind those of men in virtually all fields. Gender-stereotyped messages play a key role.

#### 13.11 What problems do U.S. non-college-bound young people face in preparing for a vocation?

- Most U.S. non-college-bound high school graduates are limited to low-paid, unskilled jobs, and many are unemployed. Work-study apprenticeships, like those widely available in Europe, would improve the transition from school to work for these young people.

## Important Terms and Concepts

basal metabolic rate (BMR) (p. 446)  
 biological aging, or senescence (p. 438)  
 cognitive-affective complexity (p. 458)  
 commitment within relativistic thinking (p. 457)  
 cross-linkage theory of aging (p. 440)  
 dualistic thinking (p. 456)

epistemic cognition (p. 456)  
 expertise (p. 458)  
 fantasy period (p. 462)  
 free radicals (p. 440)  
 postformal thought (p. 456)  
 pragmatic thought (p. 458)

realistic period (p. 462)  
 relativistic thinking (p. 457)  
 telomeres (p. 438)  
 tentative period (p. 462)

## Career Development

Establishing a Career • Women and Ethnic Minorities • Combining Work and Family

After completing her master's degree at age 26, Sharese returned to her hometown, where she and Ernie would soon be married. During their yearlong engagement, Sharese had wavered about whether to follow through. At times, she looked with envy at Heather, still unattached and free to choose from an array of options before her. After graduating from college, Heather accepted a Peace Corps assignment in a remote region of Ghana, forged a romance with another Peace Corps volunteer that she ended at the conclusion of her tour of duty, and then traveled for eight months before returning to the United States to contemplate next steps.

Sharese also pondered the life circumstances of her friend Christy and Christy's husband, Gary—married and first-time parents by their mid-twenties. Despite his good teaching performance, Gary's relationship with his high school principal deteriorated, and he quit his job at the end of his first year. A tight job market impeded Gary's efforts to find another teaching position, and financial pressures and parenthood put Christy's education and career plans on hold. Sharese wondered whether it was really possible to combine family and career.

As her wedding approached, Sharese's ambivalence intensified, and she admitted to Ernie that she didn't feel ready to marry. Ernie's admiration for Sharese had strengthened over their courtship, and he reassured her of his love. His career as an accountant had been under way for two years, and at age 28, he looked forward to marriage and starting a family. Uncertain and conflicted, Sharese felt swept toward the altar as relatives and friends began to arrive—and even as she walked down the aisle on the appointed day.

In this chapter, we take up the emotional and social sides of early adulthood. Notice that Sharese, Ernie, and Heather moved toward adult roles slowly, at times vacillating along the way. Not until their mid- to late twenties did they make lasting career and romantic choices and attain full economic independence—broadly accepted markers of adulthood that young people of previous generations reached considerably earlier. Each received financial and other forms of support from parents and other family members, which enabled them to postpone taking on adult roles. We consider whether prolonged exploration of life options has become so widespread that it merits a new developmental period—*emerging adulthood*—to describe and understand it.

Recall from Chapter 12 that identity development continues to be a central focus from the late teens into the mid-twenties (see page 410). As they achieve a secure identity, young adults seek close, affectionate ties. Yet the decade of the twenties is accompanied by a rise in feelings of personal control over events in their lives—in fact, a stronger sense of control than they may ever experience again (Ross & Mirowsky, 2012). Perhaps for this reason, like Sharese, they often fear losing their freedom. Once this struggle is resolved, early adulthood leads to new family units and parenthood, accomplished in

the context of diverse lifestyles. At the same time, young adults must master the tasks of their chosen career.

Our discussion will reveal that identity, love, and work are intertwined. In negotiating these arenas, young adults do more choosing, planning, and changing course than any other age group. When their decisions are in tune with themselves and their social and cultural worlds, they acquire many new competencies, and life is full and rewarding. ●

## A Gradual Transition: Emerging Adulthood

**14.1** Discuss emotional and social development during emerging adulthood, along with cultural influences and individual variations.

Think about your own development. Do you consider yourself to have reached adulthood? When a sample of 1,000 U.S. 18- to 29-year-olds diverse in SES and ethnicity was asked this question, the majority of those between 18 and 21 gave an ambiguous answer: “yes and no”—a proportion that declined with age as an increasing number replied with certainty, “yes” (see Figure 14.1) (Arnett & Schwab, 2013). Similar findings are evident in a wide

**FIGURE 14.1** American young people’s responses to the question, “Do you feel you have reached adulthood?” Between ages 18 and 21, the majority answered “yes and no.” Even in their late twenties, 30 percent judged that they had not completed the transition to adulthood. (From J. J. Arnett & J. Schwab, 2013, *Clark University Poll of Emerging Adults, 2012: Thriving, Struggling, and Hopeful*, p. 7, Worcester, MA: Clark University. Adapted by permission of Jeffrey Jensen Arnett.)

range of industrialized nations (Arnett, 2007a; Buhl & Lanz, 2007; Nelson, 2009; Sirsch et al., 2009). The life pursuits and subjective judgments of many contemporary young people indicate that the transition to adult roles has become so delayed and prolonged that it has spawned a new transitional period extending from the late teens to the mid- to late twenties, called **emerging adulthood**.

## Unprecedented Exploration

Psychologist Jeffrey Arnett (2011) is the leader of a movement that regards emerging adulthood as a distinct period of life—a new stage between adolescence and adulthood defined by five features: *feeling in between* (neither adolescent nor adult), *identity exploration* (especially in love, work, and worldview), *self-focused* (not self-centered but lacking obligations to others), *instability* (frequent changes in living arrangements, relationships, education, and work), and *possibilities* (able to choose among multiple life directions). As Arnett explains, emerging adults have left adolescence but are still a considerable distance from taking on adult responsibilities. Rather, young people who have the economic resources to do so explore alternatives in education, work, and personal values and behavior more intensely than they did as teenagers.

Not yet immersed in adult roles, many emerging adults can engage in activities of the widest possible scope. Because so little is normative, or socially expected, routes to adult responsibilities are highly diverse in timing and order across individuals (Côté, 2006). For example, more college students than in past generations pursue their education in a drawn-out, nonlinear way—changing majors as they explore career options, taking courses while working part-time, or interrupting school to work, travel, or participate in national or international service programs. About one-third of U.S. college graduates enter graduate school, taking even longer to settle into their desired career track (U.S. Department of Education, 2015).

As a result of these experiences, young people’s interests, attitudes, and values broaden (see page 460 in Chapter 13). Exposure to multiple viewpoints also encourages young people to look more closely at themselves. Consequently, they develop a more complex self-concept that includes awareness of their own changing traits and values over time, and self-esteem rises (Labouvie-Vief, 2006; Orth, Robins, & Widaman, 2012). Together, these developments contribute to advances in identity.

**Identity Development.** During the college years, young people refine their approach to constructing an identity. Besides exploring in *breadth* (weighing multiple possibilities and making commitments), they increasingly explore in *depth*—evaluating existing commitments (Crocetti & Meeus, 2015; Luyckx et al., 2006; Schwartz et al., 2013). For example, if you have not yet selected your major, you may be taking classes in a broad array of disciplines. Once you commit to a major, you are likely to embark on an in-depth evaluation of your choice—reflecting on your interest, motivation, and performance and on your career

prospects as you take additional classes in that field. Depending on the outcome of your evaluation, either your commitment to your major strengthens and you integrate it into your sense of self, or you return to a reconsideration of options as you search for alternative commitments.

Investigations conducted with over 6,000 university students from a diverse array of cultures in Europe, the Middle East, and Asia revealed that most cycled between in-depth evaluation of commitments and—if these fit poorly with their talents and potentials or were otherwise dissatisfying—reconsideration of commitments (Crocetti et al., 2015). Consider your own identity progress. Does it fit this *dual-cycle model*, in which identity formation is a process of feedback loops between in-depth exploration and reconsideration until you feel certain of your choices? Notice how the model helps explain the shifts between identity statuses displayed by many young people, described in Chapter 12. College students who move from in-depth exploration to certainty of commitment provide more coherent descriptions of themselves and are higher in self-esteem, psychological well-being, and academic, emotional, and social adjustment. Those who spend much time exploring in breadth or depth without making enduring commitments, or who are identity diffused (engage in no exploration), tend to be poorly adjusted—*anxious, depressed, and higher in alcohol and drug use, casual and unprotected sex, and other health-compromising behaviors* (Kunnen et al., 2008; Schwartz et al., 2011).

Many aspects of the life course that were once socially structured—marriage, parenthood, religious beliefs, and career paths—are increasingly left to individuals to decide on their own. As a result, emerging adults are required to “individualize” their identities—a process that requires a sense of self-efficacy, planfulness and purpose, determination to overcome obstacles, and responsibility for outcomes. Among young people of diverse ethnicities and SES levels, this set of qualities, termed *personal agency*, is positively related to an information-gathering cognitive style and identity exploration followed by certainty of commitments (Luyckx & Robitschek, 2014).

Nevertheless, making enduring commitments can take longer in some cultures. In Italy, for example, young people typically live at home until about age 30, even when they earn enough to live independently; most leave home only when they marry. Italians in their twenties often put identity commitments “on hold”—engaging in an extended moratorium encouraged by parents, who grant them much freedom, approval, and economic support to experiment with identity alternatives (Crocetti, Rabaglietti, & Sica, 2012). As a result, Italian emerging adults who display prolonged, in-depth exploration tend to be better adjusted than their counterparts in other cultures.

**Worldview.** Most emerging adults say that constructing a worldview, or a set of beliefs and values to live by, is essential for attaining adult status—even more important than finishing their education and settling into a career and marriage (Arnett, 2007b). Do today’s young people forge self-centered worldviews, as the descriptor “generation me” suggests?

This issue has generated heated controversy. Analyses of large, nationally representative samples of U.S. young people, collected repeatedly over several decades, suggest that compared to past generations, Millennials report greater narcissism (egotistical self-admiration) and materialism—valuing of money and leisure and reduced empathy for the less fortunate (Gentile, Twenge, & Campbell, 2010; Twenge, 2013).

But other researchers claim that generational changes in egotism and other traits are so small as not to be meaningful (Paulsen et al., 2016). And gradual, age-related gains in self-esteem extending from adolescence through emerging adulthood and into midlife are similar across generations, with average self-esteem of today’s young people no higher than that of past cohorts (Orth, Robins, & Widaman, 2012; Orth, Trzesniewski, & Robins, 2010). Over these years, adults derive a greater sense of competence from making identity commitments, entering and succeeding at their careers, having families, and becoming involved in their communities.

Furthermore, the importance to college students of attaining material wealth has not risen over the past three decades (Arnett, Trzesniewski, & Donnellan, 2013). In one investigation, the overwhelming majority of a national sample of U.S. 18- to 29-year-olds indicated that enjoyment of their work would be more important than making a lot of money, and that it was important to have a career that “does some good in the world” (Arnett & Schwab, 2013). Emerging adults do rate highly certain individualistic goals, such as career success and finding purpose in life, but these are balanced by high valuing of relationship goals, including a good marriage and strong friendships (Trzesniewski & Donnellan, 2010).

### LOOK and LISTEN

Ask 10 to 15 of your college classmates to answer the following question: What would you do if you had a million dollars? How often do respondents mention prosocial as opposed to self-centered acts?

**Civic and Political Commitments.** Evidence also supports the view that many emerging adults are committed to improving their communities, nation, and world. In a survey of 165,000 first-year students enrolled in more than 200 U.S. colleges and universities, a record number expected to participate in community service, with nearly 35 percent saying that there is “a very good chance” they will do so—double the number a generation ago (Eagan et al., 2013). Among those who expect to volunteer, the overwhelming majority actually do so within their first year (DeAngelo, Hurtado, & Pryor, 2010). Overall, emerging adults are about as likely as contemporary older adults to work with others on local projects in their communities and raise funds for charitable causes (Flanagan & Levine, 2010).

Furthermore, compared to young people in previous generations, today’s emerging adults have a stronger *pluralistic orientation*—disposition for living in a diverse society that promotes

EDUARDO CONTRERAS/UT-SAN DIEGO/ZUMAPRESS.COM

During a community event that provides services for homeless veterans, a cosmetology student shows an older adult the haircut she just gave him. Many emerging adults participate in community service and are committed to improving their world.

individual respect and equality of opportunity, regardless of race, ethnicity, gender, and sexual orientation. They are also more concerned about addressing global problems (Arnett, 2013). Overall, the intentions and behaviors of emerging adults reflect considerable caring and concern for others and civic engagement, from which they reap wide-ranging benefits—enhanced self-esteem, sense of purpose and meaning, social skills, and social networks and declines in stress, anxiety, depression, and antisocial behavior (Núñez & Flanagan, 2016).

Finally, contemporary U.S. 18- to 29-year-olds have been labeled “apathetic no shows” when it comes to voting. After declining over the 1990s, their turnout rose in the 2000s, reaching 51 percent in 2008, then dropped to 45 percent in 2012, but rose again in 2016. Throughout, participation remained below the 66 percent rate of 30-and-older citizens (Circle, 2013; Pew Research Center, 2016b). Emerging adults’ longer road to adulthood likely contributes to their comparatively low voting rate. Adult commitments and responsibilities—marriage, career progress, and financial stability—increase people’s stake in the political process, strengthening voter participation (Flanagan & Levine, 2010). Compared with older people, fewer young people vote in nearly all established democracies. Of those who do, most have at least some college education. Less educated adults of all ages feel least connected politically.

**Religion and Spirituality.** Extending a trend under way in adolescence, attendance at religious services declines further in the late teens and twenties as young people question beliefs acquired in their families and search for personally meaningful alternatives. More than one-third of U.S. 18- to 29-year-olds are unaffiliated with a particular faith, considerably more than in their parents’ generation at the same age (see Figure 14.2) (Pew Research Center, 2014a, 2015a). Many are children of baby boomer parents, who encouraged them to think for themselves.

Increasing numbers of Millennials express concern that religious (and other) institutions have become too judgmental, political, and focused on money and power.

Yet about half of U.S. young people remain stable in their religious commitment (or lack thereof) from adolescence into emerging adulthood (Pew Research Center, 2015a; Smith & Snell, 2009). And in certain ways, U.S. emerging adults are quite traditional in their religious beliefs and practices. Religion is more important in their lives than it is for young people in other developed countries. Similar to previous generations, most—including many who are unaffiliated—say they believe in God and describe themselves as religious, spiritual, or both. Furthermore, more than one-third of those who are affiliated with a religion say they are “strong” members of their faith (Pew Research Center, 2010c, 2014a). Women and ethnic minorities tend to be more religious (Barry & Abo-Zena, 2014). Of the small number of young people who increase in religiosity during the late teens and early twenties, many are women, African American, or Hispanic.

Whether or not they are involved in organized religion, many young people begin to construct their own individualized faith and, if attending college, discuss religious and spiritual beliefs and experiences more often with friends than with parents or other adults. These peer dialogues promote spiritual development (Barry & Abo-Zena, 2016; Barry & Christofferson, 2014). Often emerging adults weave together beliefs and practices from diverse sources—Eastern and Western religious traditions, science, and popular culture, including music and other media images.

**FIGURE 14.2 U.S. 18- to 29-year-olds’ religiosity across generations.** The percentage of unaffiliated young people rose substantially from the 1970s to 2014. Still, the majority express a religious affiliation. (Based on Pew Research Center, 2015a.)

Emerging adults who say their parents used an authoritative child-rearing style are more likely to hold religious or spiritual beliefs and engage in religious practices similar to their parents' (Nelson, 2014). The warmth, explanations, and autonomy granting of authoritative parenting seem to provide young people with a fuller understanding of their parents' religious ideology, along with greater freedom to evaluate it against alternatives. Consequently, they are more likely to integrate their parents' perspectives into their own worldview.

### LOOK and LISTEN

Interview several of your classmates about how their religious or spiritual beliefs and practices have changed in emerging adulthood, along with factors they see as having influenced those changes.

As with adolescents, U.S. emerging adults who are religious or spiritual tend to be better adjusted. They are higher in self-esteem and psychological well-being; less often engage in substance use, antisocial acts, or hookup and friends-with-benefits relationships; and are more often involved in community service (Barry & Christofferson, 2014; Salas-Wright, Vaughn, & Maynard, 2015). But outcomes vary: Those experiencing profound religious and spiritual struggles are at risk for physical and mental health difficulties (Magyar-Russell, Deal, & Brown, 2014). And among sexual minority young people, religiosity is less protective against poor adjustment. A possible reason is that their religious communities often do not support (and sometimes condemn) their sexual orientation (Ream & Rodriguez, 2014). They benefit from religious affiliations where sexual minority status is valued as contributing to congregational diversity.

## Cultural Change, Cultural Variation, and Emerging Adulthood

Rapid cultural change explains the recent appearance of emerging adulthood. First, entry-level positions in many fields require more education than in the past, prompting young adults to seek higher education in record numbers and thus delaying financial independence and career commitment. Second, wealthy nations with longer-lived populations have no pressing need for young people's labor, freeing those who are financially able for rich, extended exploration.

Indeed, emerging adulthood is limited to cultures that postpone entry into adult roles until the twenties. In developing nations, only a privileged minority—usually those from wealthier families who are admitted to universities—experience it, often for a shorter time span than their Western counterparts (Arnett, 2011). Furthermore, the overwhelming majority of young people in regions of Africa, Asia, and South America with traditional economies—that have few economic resources and are largely rural and farm-based—have no emerging adulthood.

With limited education, they typically enter lifelong work, marriage, and parenthood early.

In industrialized countries, many young people experience these transitional years. Typically, their families are sufficiently well-off to provide them with financial support, without which few could advance their education, explore career possibilities, or travel the country and world to—as one emerging adult put it—“experience as much as possible.” And although most emerging adults are pursuing higher education or have earned an advanced degree, some non-college-bound young people also benefit from this extended transition to adult roles (Tanner, Arnett, & Leis, 2009). But they may do so by trying out different types of work rather than college majors or travel.

Nevertheless, for low-SES youths in Western nations who are burdened by early parenthood, do not finish high school, are otherwise academically unprepared for college, or do not have access to vocational training, emerging adulthood is limited or nonexistent (see Chapters 11 and 13). Instead of excitement, exploration, and personal expansion, these individuals often alternate between unemployment and dead-end, low-paying jobs (Arnett & Tanner, 2011).

Because of its strong association with SES and higher education, some researchers reject the notion of emerging adulthood as a distinct life stage (see the Cultural Influences box on page 474). Others disagree, predicting that emerging adulthood will become increasingly common as *globalization*—the exchange of ideas, information, trade, and immigration among nations—accelerates. As globalization proceeds, gains in higher education and the formation of a common “global identity” among young people may lead to the spread of emerging adulthood (Marshall & Butler, 2016). But an emerging adulthood abundant in opportunity depends to a great extent on socioeconomic conditions.

## Risk and Resilience in Emerging Adulthood

Most young people with access to the opportunities of emerging adulthood experience it as a time of flourishing, in which they solidify beliefs and values, succeed educationally, participate in prosocial activities, and launch a career. But a sizable number flounder: Their lack of direction is evident in persisting low self-esteem; high anxiety and depression; poor academic performance; and high levels of risky behaviors (Nelson & Padilla-Walker, 2013; Smith et al., 2011). What factors might differentiate emerging adults who flourish from those who flounder?

Longitudinal research indicates that the personal attributes and social supports listed in Applying What We Know on page 475 foster successful passage through these years, as indicated by completing a college degree or vocational certification, finding and keeping a well-paying job, forging warm, stable relationships with friends and intimate partners, volunteering in one's community, and feeling generally satisfied with life (Tanner, 2016). Notice how the resources in the table overlap with ones

## Cultural Influences

### Is Emerging Adulthood Really a Distinct Stage of Development?

Although broad consensus exists that cultural change has prolonged the transition to adult roles for many young people, disagreement exists over whether these years of “emergence” should be designated a new life stage (Côté, 2014; Kloep & Hendry, 2011). Critics of the concept of emerging adulthood offer the following arguments.

First, burgeoning higher education enrollment, delayed career entry, and later marriage and parenthood are cultural trends that began as early as the 1970s in industrialized nations, only gradually becoming more conspicuous. At no time has adulthood in complex societies been attained at a distinct moment. Rather, young people in the past reached adult status earlier in some domains and later in others, just as they do today. They also may reverse direction—for example, move back to the parental home to get their bearings after finishing college or abandon a career in favor of renewed study (Côté & Bynner, 2008; du Bois-Reymond, 2016). In accord with the lifespan perspective, development is multidimensional and multidirectional for 18- to 29-year-olds as it is for adults of all ages. Transitions occur during all periods of adult life, with societal conditions heavily influencing their timing, length, and complexity.

Second, the term *emerging adulthood* fails to describe the experiences of most of the world’s youths (Nelson & Luster, 2016). In developing countries, the majority of young people—particularly women—are limited in education and marry and have children early. According to one estimate, about 1 billion individuals—nearly 70 percent of young people—follow this traditional route to adulthood (World Health Organization, 2015h). We have also seen that many low-SES youths in industrialized nations lack the academic preparation and financial resources to experience an emerging adulthood.

Third, research on emerging adulthood largely emphasizes its personal and societal benefits. But the extended exploration that defines this period might be largely a coping mechanism on the part of young people who cannot find rewarding jobs, even after college graduation. When college graduates find satisfying work enabling financial independence, most choose not to postpone these responsibilities (Arum & Roksa, 2014). Furthermore, an extended emerging adulthood is risky for those who have not developed the personal agency to make good choices and acquire adult skills (Smith et al., 2011). These young people may remain uncommitted for too long—an outcome that impedes the focused learning required for a successful work life.

Finally, the financial upheaval of the late 2000s left large numbers of bachelor’s degree holders with restricted options. In 2015, over 7 percent of recent college graduates were unemployed, and 15 percent were underemployed—in low-paid jobs not requiring a college degree (Davis, Kimball, & Gould, 2015). Thus, they remain without work experiences necessary for advancing their skills. Rather than a “natural,” self-chosen period of unparalleled opportunities, these graduates’ delayed entry into adult roles resulted from a national economic crisis. One young person, who might have been high in personal agency in a stable economy, remarked, “It has been tough finding a job that keeps me wanting to stick with something” (Kotkin, 2012).

This 22-year-old performs unskilled work for low wages. Many low-SES young people lack the academic preparation and financial resources to experience an emerging adulthood.

BLEND IMAGES - DREAMPICTURES/SHANNON FAULK

Proponents of emerging adulthood as a distinct stage respond that, though not universal, it applies to most young people in industrialized societies and is spreading in developing nations that play major roles in our global economy (Tanner & Arnett, 2011). But skeptics counter that emerging adulthood is unlikely to become prominent in developing countries with high concentrations of poverty or, in industrialized nations, among low-income youths or those not involved in higher education (du Bois-Reymond, 2016; Kloep & Hendry, 2011). And for college graduates, societal conditions can readily restrict the prospects and rewards of this period.

Critics also emphasize that in developed nations, age-graded influences have declined in favor of nonnormative influences throughout contemporary adulthood (see page 10 in Chapter 1 to review). In their view, rather than being unique, emerging adults are part of a general trend toward blurring of age-related expectations, yielding multiple transitions and increased diversity in development throughout the adult years.

## Applying what we Know

### Resources That Foster Resilience in Emerging Adulthood

TYPE OF RESOURCE	DESCRIPTION
Cognitive attributes	<ul style="list-style-type: none"> <li>Effective planning and decision making</li> <li>Information-gathering cognitive style and mature epistemic cognition</li> <li>Good school performance</li> <li>Knowledge of vocational options and necessary skills</li> </ul>
Emotional and social attributes	<ul style="list-style-type: none"> <li>Positive self-esteem</li> <li>Good emotional self-regulation and flexible coping strategies</li> <li>Good conflict-resolution skills</li> <li>Confidence in one's ability to reach one's goals</li> <li>Sense of personal responsibility for outcomes</li> <li>Persistence and effective use of time</li> <li>Healthy identity development—movement toward exploration in depth and certainty of commitment</li> <li>Strong moral character</li> <li>Sense of meaning and purpose in life, engendered by religion, spirituality, or other sources</li> <li>Desire to contribute meaningfully to one's community</li> </ul>
Social and financial supports	<ul style="list-style-type: none"> <li>Warm, autonomy-supportive relationship with parents</li> <li>Positive relationships with peers, teachers, and mentors</li> <li>Financial assistance from parents or others</li> <li>Sense of connection to social institutions, such as school, religious institution, workplace, and community center</li> </ul>

discussed in previous chapters that promote development through *resilience*, the capacity to overcome challenge and adversity. Young people with more of these resources—and with resources in all three categories—probably make an especially smooth transition to adulthood. But some emerging adults with only a few resources also fare well.

As in childhood and adolescence, certain resources strengthen others. Relationships with parents have an especially wide-ranging influence. A secure, affectionate parent–emerging adult bond that extends the balance of connection and separation established in adolescence promotes many aspects of adaptive functioning: favorable self-esteem, identity progress, successful transition to college life, higher academic achievement, and more rewarding friendships and romantic ties. Autonomy-supportive parenting in particular—an empathic approach in which parents recognize the weighty decisions the young person faces and encourage personally valued choices—is linked to emerging adults' psychological well-being (Kins et al., 2009). As one reviewer of research summed up, “What seems advantageous for emerging adults' achievement of independence is feeling connected, secure, understood, and loved in their families, and having the willingness to call on parental resources” (Aquilino, 2006, p. 201).

In contrast, parental overprotection, expressed through excessive contact and psychological control—including taking over when the young person encounters challenges—is linked to the indicators of poor adjustment we have just considered, including low self-esteem, inability to make commitments in identity formation, and increased anxiety, depression, and alcohol use (Luyckx et al., 2007; Nelson et al., 2011; Patock-Peckam & Morgan-Lopez, 2009). In another form of parenting—called *helicopter parenting* in popular culture—warm, well-intentioned parents “hover” over the emerging adult out of excessive concern for his or her well-being. They might, for example, take the young person to college but refuse to leave and contact professors to discuss the young person's grades. Perhaps because helicopter parenting is motivated by strong parental affection and involvement, it is not associated with the negative outcomes just noted. But it is related to reduced school engagement (going to class, completing assignments) (Padilla-Walker & Nelson, 2012). And it likely interferes with emerging adults' ability to acquire the skills they need to act on their own.

Finally, exposure to multiple negative life events—family conflict, abusive intimate relationships, repeated romantic break-ups, academic or employment difficulties, and financial strain—undermines development, even in emerging adults whose

childhood and adolescence prepared them well for this transition (Tanner, 2016). In sum, supportive family, school, and community environments are crucial, just as they were at earlier ages. The majority of young people with these resources are optimistic about their future (Arnett & Schwab, 2013). Now let's turn to theories of psychosocial development in early adulthood.

## Ask yourself

**CONNECT** How are resources that foster resilience in emerging adulthood similar to those that promote resilience in childhood and adolescence? (See pages 10–11 in Chapter 1, page 360 in Chapter 10, and page 422 in Chapter 12.)

**APPLY** List supports that your college environment offers emerging adults in its health and counseling services, academic advising, residential living, and extracurricular activities. How does each help young people transition to adult roles?

**REFLECT** Should emerging adulthood be considered a distinct developmental stage? Why or why not?

## Erikson's Theory: Intimacy versus Isolation

**14.2** According to Erikson, what personality changes take place during early adulthood?

Erikson's vision has influenced all contemporary theories of adult personality development. His psychological conflict of early adulthood is **intimacy versus isolation**, evident in the young

person's thoughts and feelings about making a long-term commitment to an intimate partner and in close, mutually gratifying friendships.

As Sharese discovered, building an emotionally fulfilling romantic bond is challenging. Most young adults are still grappling with identity issues. Yet intimacy requires that they give up some of their independent self and redefine their identity to include both partners' values and interests. Those in their late teens through mid-twenties frequently say they don't feel ready for a lasting romantic tie, mentioning concerns about career and financial security and emotional readiness, including limits on their freedom (Arnett, 2015; Willoughby & Carroll, 2016). During their first year of marriage, Sharese separated from Ernie twice as she tried to reconcile her desire for self-determination with her desire for intimacy. Maturity involves balancing these forces. Without intimacy, young adults face the negative outcome of Erikson's early adulthood stage: loneliness and self-absorption. Ernie's patience and stability helped Sharese realize that committed love requires generosity and compromise but not total surrender of the self.

Research confirms that—as Erikson emphasized—a secure identity fosters attainment of intimacy. Among large samples of college students, identity achievement was positively correlated with fidelity (loyalty in relationships) and love, for both men and women. In contrast, identity moratorium—exploration without commitment—was negatively associated with fidelity and love (Markstrom et al., 1997; Markstrom & Kalmanir, 2001). Other studies show that advanced identity development strongly predicts involvement in a deep, committed love partnership or readiness to establish such a partnership (Beyers & Seiffge-Krenke, 2010; Montgomery, 2005).

In friendships and work ties, too, young people who have achieved intimacy are cooperative, agreeable, communicative, and accepting of differences in background and values (Barry, Madsen, & DeGrace, 2016). In contrast, those with a sense of isolation hesitate to form close ties because they fear loss of their own identity, tend to compete rather than cooperate, are not accepting of differences, and are easily threatened when others get too close.

Erikson believed that successful resolution of intimacy versus isolation prepares the individual for the middle adulthood stage, which focuses on *generativity*—caring for the next generation and helping to improve society. But as noted previously, few adults follow a fixed series of tasks tied neatly to age. Some aspects of generativity—childbearing and child rearing, as well as contributions to society through work and community service—are under way in the twenties and thirties. Still, in line with Erikson's ideas, high friendship or romantic intimacy in early adulthood does predict a stronger generative orientation (Mackinnon, De Pasquale, & Pratt, 2015).

In sum, identity, intimacy, and generativity are concerns of early adulthood, with shifts in emphasis that differ among individuals. Recognizing that Erikson's theory provides only a broad sketch of adult personality development, other theorists elaborated on his stage approach, adding detail.

## Other Theories of Adult Psychosocial Development

**14.3** Describe and evaluate Levinson's and Vaillant's psychosocial theories of adult personality development.

**14.4** What is the social clock, and how does it affect development in adulthood?

In the 1970s, growing interest in adult development led to several widely read books on the topic. Daniel Levinson's *The Seasons of a Man's Life* (1978) and *The Seasons of a Woman's Life* (1996), and George Vaillant's *Adaptation to Life* (1977), *Aging Well* (2002), and *Triumphs of Experience* (2012) present psychosocial theories in the tradition of Erikson.

### Levinson's Seasons of Life

On the basis of in-depth biographical interviews with 35- to 45-year-old men—and, later, similar interviews with women in the same age range—Levinson (1978, 1996) depicted adult development as a sequence of qualitatively distinct eras (or “seasons”) coinciding with Erikson's stages and separated by *transitions*. The *life structure*, a key concept in Levinson's theory, is the underlying design of a person's life, consisting of relationships with individuals, groups, and institutions. Of its many components, usually only a few, relating to family, close friendships, and occupation, are central.

Levinson found that during the transition to early adulthood, most young people constructed a *dream*—an image of them-

MARC ROMANELLI/GETTY

A furniture designer teaches a new technique to a younger coworker. For young people starting out in a career, an experienced colleague can be an especially effective mentor, serving as a role model and guide in overcoming challenges.

selves in the adult world that guides their decision making. For men, the dream usually emphasized achievement in a career, whereas most career-oriented women had “split dreams” in which both marriage and career were prominent—findings confirmed in subsequent investigations (Heppner, 2013). Young adults also formed a relationship with a *mentor* who facilitated realization of their dream—often a senior colleague at work but occasionally a more experienced friend, neighbor, or relative. According to Levinson, men oriented toward high-status careers spent their twenties acquiring professional skills, values, and credentials. In contrast, for many women, career development extended into middle age.

Around age 30, a second transition occurred: Young people who had been preoccupied with career and were single usually focused on finding a life partner, while women who had emphasized marriage and family often developed more individualistic goals. For example, Christy, who had dreamed of becoming a professor, finally earned her doctoral degree in her mid-thirties and secured a college teaching position.

To create an early adulthood culminating life structure, men usually “settled down” by focusing on certain relationships and aspirations, in an effort to establish a niche in society consistent with their values, whether those were wealth, prestige, artistic or scientific achievement, or forms of family or community participation. In his late thirties, Ernie became a partner in his firm, coached his son's soccer team, and was elected treasurer of his church. He paid less attention to travel and playing the guitar than previously.

Many women, however, remained unsettled in their thirties, often because they added an occupational or relationship commitment. When her two children were born, Sharese felt torn between her research position in the state health department and her family. She took three months off after the arrival of each baby. When she returned to work, she did not pursue attractive administrative openings that required travel and time away from home. And shortly after Christy began teaching, she and Gary divorced. Becoming a single parent while starting her professional life introduced new strains.

### Vaillant's Adaptation to Life

Vaillant (1977) followed the development of nearly 250 men born in the 1920s, selected for study while they were students at a competitive liberal arts college. Participants were interviewed extensively while in college and answered lengthy questionnaires during each succeeding decade. Then Vaillant (2002, 2012) conducted periodic interviews with them about work, family, and physical and mental health at ages 47, 60, 70, and 85.

Looking at how the men altered themselves and their social world to adapt to life, Vaillant—like Levinson—built on Erikson's stages. After focusing on intimacy concerns in their twenties, the men turned to career consolidation in their thirties. During their forties, they became more generative. In their fifties and sixties, they extended that generativity; they became “keepers of meaning,” expressing a deep need to preserve and pass on

cultural traditions and lessons learned from life experience. Finally, in late adulthood, the men became more spiritual and reflective about the meaning of life. In a subsequent lifelong study of a sample of well-educated women, Vaillant (2002) identified a similar series of changes.

Nevertheless, the developmental patterns Vaillant and Levinson described are based largely on interviews with people born in the first few decades of the twentieth century, many of whom were educationally and economically advantaged. As our discussion of emerging adulthood illustrates, development is far more variable today—so much so that researchers increasingly doubt that adult psychosocial changes can be organized into distinct stages. Rather, people may assemble the themes and dilemmas identified by these theorists into individualized arrangements, in a *dynamic system* of interacting biological, psychological, and social forces.

## The Social Clock

As we have seen, cultural changes from one generation to the next can affect the life course. Yet all societies have some kind of **social clock**—age-graded expectations for major life events, such as beginning a first job, getting married, birth of the first child, buying a home, and retiring (Neugarten, 1979). Among economically better-off young people, finishing one's education, marrying, and having children occur much later in the lifespan than they did a generation or two ago. Furthermore, large departures from social-clock life events have become increasingly common.

These conditions can create intergenerational tensions if parents expect their young-adult children to attain adult milestones on an outdated schedule. Young adults may also feel distressed because their own timing of major milestones is not widely shared by their contemporaries or supported by current

public policies, thereby weakening availability of both informal and formal social supports (Settersten, 2007). And while rendering greater flexibility and freedom to young people's lives, an ill-defined social clock likely causes them to feel inadequately grounded—unsure of what others expect and of what to expect of themselves.

### LOOK and LISTEN

Describe your social clock, listing major life events along with the age you expect to attain each. Then ask a parent and/or grandparent to recall his or her own early adulthood social clock. Analyze generational differences.

In sum, following a social clock of some kind seems to foster confidence and social stability because it guarantees that young people will develop skills, engage in productive work, and gain in understanding of self and others. In contrast, “crafting a life of one's own,” whether self-chosen or the result of circumstances, is risky—more prone to breakdown (Settersten, 2007, p. 244). With this in mind, let's take a closer look at how men and women traverse major tasks of young adulthood.

### Ask yourself

**CONNECT** Return to pages 409–410 in Chapter 12 and review the contributions of exploration and commitment to a mature identity. Using the two criteria, explain why identity achievement is positively related to attainment of intimacy (fidelity and love), whereas identity moratorium is negatively predictive.

**APPLY** In view of contemporary changes in the social clock, explain Sharese's conflicted feelings about marrying Ernie.

**REFLECT** Describe your early adulthood dream. Then ask a friend or classmate of the other gender to describe his or her dream, and compare the two. Discuss the extent to which they are consistent with Levinson's findings.

VSTOCK LLC/TANVA CONSTANTINE/GETTY IMAGES

Because the social clock has become increasingly flexible, this 30-year-old attorney, committed to her demanding career, may not feel pressure to conform to a strict timetable for major life events such as marriage and parenthood.

## Close Relationships

**14.5** Describe factors affecting mate selection, the components of romantic love, and the changing forms of love as relationships develop, noting cultural variations.

**14.6** Describe young adults' friendships and sibling relationships and their influence on psychological well-being.

To establish an intimate tie, people must find a partner and build an emotional bond that they sustain over time. Although young adults are especially concerned with romantic love, the need for intimacy can also be satisfied through other relationships involving mutual commitment—with friends, siblings, and co-workers.

## Romantic Love

At a party during her third year of college, Sharese fell into conversation with Ernie, a senior and one of the top students in her government class. Sharese had already noticed Ernie in class, and as they talked, she discovered that he was as warm and interesting as he had seemed from a distance. Ernie found Sharese to be lively, intelligent, and attractive. By the end of the evening, the two realized that they had similar opinions on important social issues and liked the same leisure activities. They began dating steadily. Six years later, they married.

Finding a life partner is a major milestone of early adult development, with profound consequences for self-concept and psychological well-being. As Sharese and Ernie's relationship reveals, it is also a complex process that unfolds over time and is affected by a variety of events.

**Selecting a Mate.** Recall from Chapter 13 that intimate partners generally meet in places where they are likely to find people of their own age, level of education, ethnicity, and religion, or they connect through online dating services. People usually select partners who resemble themselves in other ways—attitudes, personality, educational plans, intelligence, mental health, physical attractiveness, and even height (Butterworth & Rodgers, 2006; Gorchoff, 2016; Lin & Lundquist, 2013; Watson et al., 2004). Romantic partners sometimes have complementary personality traits—one self-assured and dominant, the other hesitant and submissive. Because this difference permits each to sustain their preferred style of behavior, it contributes to compatibility (Sadler, Ethier, & Woody, 2011). But partners differing in other ways generally are not complementary! For example, a warm, agreeable person and an emotionally cool person usually react with discomfort to each other. Overall, little support exists for the idea that “opposites attract” (Furnham, 2009). Rather, partners who are similar in personality and other attributes tend to be more satisfied with their relationship and more likely to stay together.

Nevertheless, in choosing a long-term partner, men and women differ in the importance they place on certain characteristics. In research carried out in diverse industrialized and developing countries, women assign greater weight to financial status, intelligence, ambition, and moral character, whereas men place more emphasis on physical attractiveness and domestic skills. In addition, women prefer a same-age or slightly older partner, men a younger partner (Buss et al., 2001; Conroy-Beam et al., 2015).

According to an evolutionary perspective, because their capacity to reproduce is limited, women seek a mate with traits, such as earning power and emotional commitment, that help ensure children's survival and well-being. In contrast, men look for a mate with traits that signal youth, health, sexual pleasure, and ability to give birth to and care for offspring. As further evidence for this difference, men often want a relationship to move quickly toward physical intimacy (Buss, 2012). Women, in contrast, prefer to take time to achieve psychological intimacy.

In an alternative view, gender roles, jointly influenced by evolutionary and cultural pressures, affect criteria for mate

selection. Beginning in childhood, men learn to be assertive and independent—behaviors needed for success in the work world. Women acquire nurturant behaviors, which facilitate caregiving. Then each sex learns to value traits in the other that fit with this traditional division of labor (Eagly & Wood, 2012, 2013). In support of this perspective, in cultures and in younger generations experiencing greater gender equity, men and women are more alike in their mate preferences. For example, compared with men in China and Japan, American men place more emphasis on their mate's financial prospects, less on her domestic skills. Also, when either male or female young adults are asked to imagine themselves as a future homemaker, their preferences for a good provider and an older partner strengthen (Eagly, Eastwick, & Johannesen-Schmidt, 2009).

But neither men nor women put good looks, earning power, and mate's age relative to their own at the top of their wish list. Rather, they place a higher value on attributes that contribute to relationship satisfaction: mutual attraction, caring, dependability, emotional maturity, and a pleasing disposition (Toro-Morn & Sprecher, 2003). Nevertheless, men continue to emphasize physical attractiveness more than women do, and women earning capacity more than men do. Furthermore, these gender differences—along with gender similarity in desire for a caring partner—also characterize gay men and lesbians (Impett & Peplau, 2006; Lawson et al., 2014). In sum, both biological and social forces contribute to mate selection.

As the Social Issues: Health box on page 480 reveals, young people's choice of an intimate partner and the quality of their relationship also are affected by memories of their early parent-child bond. Finally, for romance to lead to a lasting partnership, it must happen at the right time. Two people may be right for each other, but if one or both do not feel ready to marry, the relationship is likely to dissolve.

**The Components of Love.** How do we know that we are in love? Robert Sternberg's (2006) **triangular theory of love** identifies three components—passion, intimacy, and commitment—that shift in emphasis as romantic relationships develop. *Passion*, the desire for sexual activity and romance, is the physical- and psychological-arousal component. *Intimacy* is the emotional component, consisting of warm, tender communication and caring, self-disclosure, plus a desire for the partner to reciprocate. *Commitment*, the cognitive component, leads partners to decide that they are in love and to maintain that love.

At the beginning of a relationship, **passionate love**—intense sexual attraction—is strong. Gradually, passion declines in favor of intimacy and commitment, which form the basis for two additional forms of love. The first is **companionate love**—warm, trusting affection and valuing of the other (Sprecher & Regan, 1998). The second, and perhaps the most fundamental type of love in any deeply satisfying close relationship, is **compassionate love**—concern for the other's well-being, expressed through caring efforts to alleviate the other's distress and promote the other's growth and flourishing (Berscheid, 2010; Sprecher & Fehr, 2005).

Romantic partners' self-reports reveal that expressions of these types of love are moderately to highly correlated, with each

## Social Issues: Health

### Childhood Attachment Patterns and Adult Romantic Relationships

In Bowlby's ethological theory of attachment, the early attachment bond leads to an *internal working model*, or set of expectations about attachment figures, that serves as a guide for close relationships throughout life. Adults' evaluations of their early attachment experiences are related to their parenting behaviors—specifically, to the quality of attachments they build with their children (see page 202 in Chapter 6). Additional evidence indicates that recollections of childhood attachment patterns predict romantic relationships in adulthood.

In studies carried out in Australia, Israel, and the United States, researchers asked people about their early parental bonds (attachment history), their attitudes toward intimate relationships (internal working model), and their actual experiences with romantic partners. In a few instances, investigators also observed couples' behaviors. Consistent with Bowlby's theory, adults' memories and interpretations of childhood attachment patterns were good indicators of internal working models and relationship experiences. (To review patterns of attachment, see page 198.)

#### Secure Attachment

Adults who described their attachment history as secure (warm, loving, and supportive parents) had internal working models that reflected this security. They viewed themselves as likable and easy to get to know, were comfortable with intimacy, and rarely worried about abandonment. They characterized their most important love relationship in terms of trust, happiness, and friendship (Cassidy, 2001). Their behaviors toward their partner were empathic and supportive and their conflict resolution strategies constructive. They were also at ease in turning to their partner for comfort and assistance and reported mutually initiated, enjoyable sexual activity (Collins & Feeney, 2010; Pietromonaco & Beck, 2015).

#### Avoidant Attachment

Adults who reported an avoidant attachment history (demanding, disrespectful, and critical parents) displayed internal working models that stressed independence, mistrust of love partners, and anxiety about people getting too

close. They were convinced that others disliked them and that romantic love is hard to find and rarely lasts. Jealousy, emotional distance, lack of support in response to their partner's distress, and little enjoyment of physical contact pervaded their most important love relationship (Pietromonaco & Beck, 2015). Avoidant adults often deny attachment needs through casual sexual encounters (Genzler & Kerns, 2004; Sprecher, 2013). They endorse many unrealistic beliefs about relationships—for example, that partners cannot change, that men's and women's needs differ, and that “mind reading” is expected (Stackert & Bursik, 2003).

#### Resistant Attachment

Adults recalling a resistant attachment history (parents who responded unpredictably and unfairly) presented internal working models in which they sought to merge completely with another person (Cassidy, 2001). At the same time, they worried that their desire for intense intimacy would overwhelm others, who really did not love them and would not want to stay with them. Their most important love relationship was riddled with jealousy, emotional highs and lows, and desperation about whether the partner would return their affection (Collins & Feeney, 2010). Resistant adults, though offering support, do so in ways that fit poorly with their partner's needs. They are also quick to express fear and anger, and they disclose information about themselves at inappropriate times (Pietromonaco & Beck, 2015).

Are adults' descriptions of their childhood attachment experiences accurate, or are they distorted or even completely invented? In several longitudinal studies, quality of parent-child interactions, observed or assessed through family interviews 5 to 23 years earlier, were good predictors of internal working models and romantic-relationship quality in early adulthood (Donnellan, Larsen-Rife, & Conger, 2005; Roisman et al., 2001; Zayas et al., 2011). These findings suggest that adult recollections bear some resemblance to actual parent-child experiences. However, attributes of the current partner also influence internal working models and intimate ties. When generally insecure individuals manage to form a secure representation of

COURTESY OF CAROL ALPER

Did the internal working model constructed by this baby, held tenderly by his father, influence the relationship he later forged with his wife? Research indicates that early attachment pattern is one of several factors associated with the quality of later intimate ties.

their partner, they report stronger feelings of affection and concern and reduced relationship conflict and anxiety (Simpson & Overall, 2014; Sprecher & Fehr, 2011).

In sum, negative parent-child experiences can be carried forward into adult close relationships. At the same time, internal working models are continuously “updated.” When adults with a history of unhappy love lives have a chance to form a satisfying intimate tie, they may revise their internal working model. As the new partner approaches the relationship with a secure state of mind and sensitive, supportive behavior, the insecure partner may reappraise her expectations and respond in kind. This reciprocity creates a feedback loop through which a revised, more favorable internal working model, along with mutually gratifying interaction, persists over time.

PEOPLEIMAGES.COM/GETTY IMAGES

Romantic relationships become more intimate, committed, satisfying, and long-lasting as they move from passionate love into the trusting affection of companionate love and the caring bond of compassionate love.

helping to sustain the relationship (Fehr & Sprecher, 2013). Early passionate love is a powerful predictor of whether partners keep dating. Without the quiet intimacy, predictability, and shared attitudes and values of companionate love, most romances eventually break up (Hendrick & Hendrick, 2002). And the combination of intimacy and commitment inherent in compassionate love is strongly linked to partners' relational happiness and plans to remain together over the long term (Fehr, Harasymchuk, & Sprecher, 2014).

An ongoing relationship requires effort by both partners. Research on newlyweds' feelings and behavior over the first few years of marriage reveals that despite couples' optimistic forecasts that their marital satisfaction would remain stable or improve, partners gradually felt less "in love" and less pleased with married life (Huston et al., 2001; Lavner, Karney, & Bradbury, 2013). A variety of factors contributed, including a sharp drop in time spent talking to each other and expressing affection. Joint leisure pursuits gave way to more household tasks and chores and, therefore, fewer enjoyable times together. Also, when discussing areas of conflict, partners declined in accurate reading of each other's thoughts and feelings (Kilpatrick, Bissonnette, & Rusbult, 2002). Perhaps after an increasing number of such interactions, they tried less hard to grasp the other's point of view and resorted to well-established habits, such as giving in or withdrawing.

But couples whose relationships endure generally report that they love each other more than they did earlier (Sprecher, 1999). In the transformation from a passionate to a companionate and compassionate bond, *commitment* may be the component of love that determines whether a relationship survives. Communicating that commitment in ways that strengthen *intimacy*—through warmth, attentiveness, understanding, acceptance, and respect—strongly predicts relationship maintenance and satisfaction (Lavner & Bradbury, 2012; Neff & Karney, 2008). For example,

Sharese's doubts about getting married subsided largely because of Ernie's expressions of commitment. He assured her that he understood her needs and would support her career aspirations and individuality in other ways. Sharese returned Ernie's sentiments, and the strength of their bond deepened.

An important feature of expressing commitment is constructive conflict resolution—directly expressing wishes and needs, listening patiently, asking for clarification, compromising, accepting responsibility, forgiving one's partner, using humor, and otherwise avoiding the escalation of negative interaction sparked by criticism, contempt, defensiveness, and stonewalling (Dennison, Koerner, & Segrin, 2014; Gottman, Driver, & Tabares, 2015). In a longitudinal study, newlyweds' negativity during problem solving predicted marital dissatisfaction and divorce over the following decade (Sullivan et al., 2010). Those who displayed little concern and caring often resorted to anger and contempt when dealing with problems.

Although the capacity for constructive conflict resolution is a vital ingredient of enduring marriages, a tender, affectionate bond seems to energize that capacity, motivating couples to resolve conflicts in ways that preserve a gratifying sense of intimacy. Compared with women, men are less skilled at communicating in ways that foster intimacy, offering less comfort and helpful support in their close relationships. Men also tend to be less effective at negotiating conflict, frequently avoiding discussion (Burlison & Kunkel, 2006; Wood, 2009).

Sexual minority and heterosexual couples are similar in expressions of commitment, intimacy, and conflict and in the contributions of each to relationship satisfaction (Kurdek, 2004). But for lesbian and gay couples, widespread social stigma complicates the process of forging a gratifying, committed bond. Those who worry most about being stigmatized or harbor negative attitudes toward their own sexual orientation report lower-quality and less enduring love relationships (Mohr & Daly, 2008; Mohr & Fassinger, 2006). Applying What We Know on page 482 lists ways that all couples can help keep the embers of love aglow in a romantic partnership.

**Culture and the Experience of Love.** Passionate love, with its intense feelings of ecstasy and longing, is recognized in virtually all contemporary cultures, though its importance varies. Passion, which forms the basis for romantic love, along with respect for the other's unique qualities, became the dominant basis for marriage in twentieth-century Western nations as the value of individualism strengthened (Hatfield, Rapson, & Martel, 2007). Trying to satisfy dependency needs through a close relationship is regarded as immature.

This Western view contrasts sharply with the perspectives of Eastern cultures. In Japan, for example, lifelong dependency is accepted and viewed positively. The Japanese word *amae*, or love, means "to depend on another's benevolence." The traditional Chinese interdependent view defines the self through role relationships—son or daughter, brother or sister, husband or wife. Feelings of affection are distributed across a broad social network, reducing the emotional intensity of any one relationship.

## Applying what we Know

### Keeping Love Alive in a Romantic Partnership

SUGGESTION	DESCRIPTION
Make time for your relationship.	To foster relationship satisfaction and a sense of being “in love,” plan regular times to be together.
Tell your partner of your love.	Express warmth and affection, including the powerful words “I love you,” at appropriate times. These messages increase perceptions of commitment, strengthen intimacy, and encourage your partner to respond in kind.
Be available to your partner in times of need.	Provide emotional support, giving of yourself when your partner is distressed and supporting your partner in attaining personal goals.
Communicate constructively and positively about relationship problems.	When you or your partner is dissatisfied, suggest ways of overcoming difficulties, and ask your partner to collaborate in choosing and implementing a course of action. Avoid the four enemies of relationship satisfaction: criticism, contempt, defensiveness, and stonewalling.
Show an interest in important aspects of your partner’s life.	Ask about your partner’s work, friends, family, and leisure pursuits and express appreciation for his or her special abilities and achievements. In doing so, you grant your partner a sense of being valued.
Confide in your partner.	Share innermost feelings, keeping intimacy alive.
Forgive minor offenses and try to understand major offenses.	Whenever possible, overcome feelings of anger through forgiveness. In this way, you acknowledge unjust behavior but avoid becoming preoccupied with it.

In choosing a lifelong partner, Chinese and Japanese young people are expected to consider obligations to others, especially parents. Compared with their Western counterparts, college students of Asian heritage place less emphasis on physical attraction and deep emotion and more weight on companionship and practical matters—similarity of background, career promise, and likelihood of being a good parent (Hatfield, Rapson, & Martel, 2007).

Still, even in Eastern countries such as China, India, and Japan where arranged marriages are still fairly common, parents and prospective brides and grooms consult one another before moving forward. If parents try to force their children into a marriage with little chance of love, most of the time children resist, emphasizing the importance of love (Hatfield, Mo, & Rapson,

2015). Nevertheless, arranged marriages offer certain advantages in the cultures in which they occur, including greater family and community approval and support.

Furthermore, many arranged marriages succeed, with marital satisfaction as high as, and occasionally higher than, in self-chosen marriages (Madathil & Benshoff, 2008; Schwartz, 2007). In interviews with arranged-marriage couples from diverse countries who reported that their love gradually grew over time, the contributing factor most often mentioned was commitment (Epstein, Pandit, & Thakar, 2013). Participants explained that commitment helped bring about other qualities that strengthened their love, including good communication, accommodation (caring and concern), and pleasurable physical intimacy. A substantial number stated that building love in their marriages was an intentional act. Although not a defense of arranged marriages, the findings suggest conditions under which love between self-chosen newlyweds might be induced to grow, rather than decline as it typically does.

## Friendships

Like romantic partners and childhood friends, adult friends are usually similar in age, sex, and SES—factors that contribute to common interests, experiences, and needs and therefore to the pleasure derived from the relationship. As in earlier years, friends in adulthood enhance self-esteem and psychological well-being through affirmation, acceptance, autonomy support (permitting disagreement and choice), and support in times of stress (Barry, Madsen, & DeGrace, 2016). Friends also make life more interesting by expanding social opportunities and access to knowledge and points of view.

Trust, intimacy, and loyalty, along with shared interests and values and enjoyment of each other’s company, continue to be

© PEP ROIG/ALAMY

An Indian brahmin (priest) marries a young couple. Although arranged marriages are still common in some Eastern countries, many couples emphasize the importance of love, which often grows over time.

important in adult friendships, as they were in adolescence (Blieszner & Roberto, 2012). Sharing thoughts and feelings is sometimes greater in friendship than in marriage, although commitment is less strong as friends come and go over the life course. Even so, some adult friendships continue for many years, at times throughout life. Seeing each other often contributes to friendship continuity. Partly because female friends get together more often than male friends, adult friendship ties tend to be longer-lasting among women (Sherman, de Vries, & Lansford, 2000).

Because of a dramatic rise in social media use, today's friendships are no longer as constrained by physical proximity. Among 18- to 29-year-olds, 90 percent use social media sites (Pew Research Center, 2016d). Consequently, networks of "friends" have expanded. These include friends who meet through online groups and may never meet in person but who share interests and offer emotional support (Lefkowitz, Vukman, & Loken, 2012). As yet, little is known about the role of these online ties in adults' lives.

Do social media sites lead young adults to form a large number of acquaintances at the expense of intimate friendships? Research reveals that people with 500 or more Facebook friends actually interact individually—by "liking" posts, leaving comments on walls, or engaging in chats—with far fewer. Among these large-network Facebook users, men engaged in one-on-one communication with an average of just 10 friends, women with just 16 (Henig & Henig, 2012). Facebook use was associated with an increase in passive tracking of casual relationships but no change in the number of core friendships.

### LOOK and LISTEN

Ask your friends on social media to indicate the size of their online network along with the number of friends they interacted with individually during the past month. Do large-network users have only a limited number of core friendships?

**Same-Sex Friendships.** Throughout life, women have more intimate same-sex friendships than men. Extending a pattern evident in childhood and adolescence, female friends often say they prefer to "just talk," whereas male friends say they like to "do something" such as play sports (see Chapter 12, page 423). Barriers to intimacy between male friends include competitiveness, which may make men unwilling to disclose weaknesses. Because of greater intimacy and give-and-take, women generally evaluate their same-sex friendships more positively than men do. But they also have higher expectations of friends (Blieszner & Roberto, 2012). Thus, they are more disapproving if friends do not meet their expectations.

Of course, individual differences exist in friendship quality. The longer-lasting men's friendships are, the closer they become and the more they include disclosure of personal information (Sherman, de Vries, & Lansford, 2000). Furthermore, involvement in family roles affects reliance on friends. For single adults, friends are the preferred companions and confidants. The more intimate young adults' same-sex friendships are in terms of

© OJO IMAGES LTD/ALAMY

Male friends usually like to "do something" together, whereas female friends prefer to "just talk." But the longer-lasting men's friendships are, the more intimate they become, increasingly including disclosure of personal information.

warmth, social support, and self-disclosure, the more satisfying and longer-lasting the relationship and the greater its contribution to psychological well-being (Perlman, Stevens, & Carcedo, 2015). Gay and lesbian romantic relationships often develop out of close same-sex friendships, with lesbians, especially, forging compatible friendships before becoming involved romantically (Diamond, 2006).

As they develop romantic ties and marry, young adults—especially men—direct more of their disclosures toward their partners. Still, friendships continue to be vital contexts for personal sharing throughout adulthood. A best friendship can augment well-being when a marriage is not fully satisfying (but not when the marriage is low in quality) (Birditt & Antonucci, 2007).

**Other-Sex Friendships.** From the college years through career exploration and settling into work roles, other-sex friendships increase. After marriage, they decline for men but continue to rise for women, who more often form them in the workplace. Highly educated, employed women have the largest number of other-sex friends. Through these relationships, young adults often gain in companionship and self-esteem and learn about masculine and feminine styles of intimacy (Bleske & Buss, 2000). Because men confide especially easily in their female friends, such friendships offer them a unique opportunity to broaden their expressive capacity. And women sometimes say male friends offer objective points of view on problems and situations—perspectives not available from female friends (Monsour, 2002).

Many people try to keep other-sex friendships platonic to safeguard their integrity. But sometimes the relationship changes into a romantic bond. When a solid other-sex friendship does evolve into a romance, it may be more stable and enduring than a romantic relationship formed without a foundation in friendship. And emerging adults, especially, are flexible about people they

include in their friendship networks (Barry, Madsen, & DeGrace, 2016). After a breakup, they may even keep a former romantic partner on as a friend.

**Siblings as Friends.** Whereas intimacy is essential to friendship, commitment—willingness to maintain a relationship and care about the other—is the defining characteristic of family ties. As young people marry and invest less time in developing a romantic partnership, siblings—especially sisters whose earlier bond was positive—become more frequent companions than in adolescence (Birditt & Antonucci, 2007). Often, friend and sibling roles merge. For example, Sharese described Heather’s practical assistance—helping with moving and running errands during an illness—in kinship terms: “She’s like a sister to me. I can always turn to her.” And adult sibling ties resemble friendships, in which the main concerns are staying in contact, offering social support, and enjoying being together.

A childhood history of intense parental favoritism and sibling rivalry can disrupt sibling bonds in adulthood (Panish & Stricker, 2002). But when family experiences have been positive, relationships between adult siblings can be especially close and are important sources of psychological well-being (Sherman, Lansford, & Volling, 2006). A shared background promotes similarity in values and perspectives and the possibility of deep mutual understanding.

In families with five to ten siblings, common in industrialized nations in the past and still widespread in some cultures, close sibling bonds may replace friendships (Fuller-Iglesias, 2010). One 35-year-old with five siblings, who all—with their partners and children—resided in the same small city, remarked, “With a family like this, who needs friends?”

## Ask yourself

**CONNECT** How might recollections and evaluations of childhood attachment history, discussed on page 480, affect intimate partners’ readiness to develop companionate and compassionate love?

**APPLY** Compared to two years earlier, when they had just met, Mindy and Graham reported an increase in relationship satisfaction. What changes in love and features of communication might have deepened their bond?

**REFLECT** Do you have a nonromantic, close other-sex friendship? If so, how has it enhanced your emotional and social development?

## The Family Life Cycle

**14.7** Trace phases of the family life cycle that are prominent in early adulthood, and cite factors that influence these phases today.

For most young people, the life course takes shape within the **family life cycle**—a series of phases characterizing the development of most families around the world. In early adulthood,

people typically live on their own, marry, and bear and rear children. In middle age, as their children leave home, their parenting responsibilities diminish. Late adulthood brings retirement, growing old, and (more often for women) death of one’s spouse (McGoldrick & Shibusawa, 2012). Stress tends to be greatest during transitions between phases, as family members redefine and reorganize their relationships.

But as our earlier discussion made clear, we must be careful not to view the family life cycle as a fixed progression. Wide variations exist in the sequence and timing of its phases—high rates of out-of-wedlock births, delayed marriage and parenthood, divorce, and remarriage, among others. And some people, voluntarily or involuntarily, do not experience all family life-cycle phases. Still, the family life-cycle model is useful. It offers an organized way of thinking about how the family system changes over time and the impact of each phase on the family unit and the individuals within it.

## Leaving Home

During her first semester of college, Sharese noticed a change in how she related to her mother. She found it more enjoyable to discuss daily experiences and life goals, sought advice and listened with greater openness, and expressed affection more freely.

Departure from the parental home is a major step toward assuming adult responsibilities. The average age of leaving has risen since the 1960s; today, it resembles the departure age at the beginning of the twentieth century. But reasons for coresidence have changed: Early twentieth-century young adults resided with parents so they could contribute to the family economy. Twenty-first-century young people living at home are typically financially dependent on their parents. This trend toward later home-leaving is evident in most industrialized nations, though substantial variation in timing exists. Because government support is available, young adults in the Scandinavian countries move out relatively early (Furstenberg, 2010). In contrast, cultural traditions in Mediterranean countries promote lengthy coresidence, extending into the thirties.

Departures for education tend to occur at earlier ages, those for full-time work and marriage later. Because the majority of U.S. young adults enroll in higher education, many leave home around age 18. Those from divorced, single-parent homes tend to be early leavers, perhaps because of family stress (Seiffge-Krenke, 2013). Compared with the previous generation, fewer North American and Western European young people leave home to marry; more do so just to be “independent”—to express their adult status.

Slightly over half of U.S. 18- to 25-year-olds return to their parents’ home for brief periods after first leaving (U.S. Census Bureau, 2015a). Usually, role transitions, such as the end of college or military service, bring young people back. But tight job markets, high housing costs, mental health problems, failures in work or love, or desire by young people launching their work lives to conserve economic resources can also prompt a temporary return home (Sandberg-Thoma, Snyder, & Jang, 2015). Also, young people who left because of family conflict often return—largely because they were not ready for independent living.

SOFIE DELAUW/GETTY IMAGES

A family dinner in this Italian home includes two grown sons. Mediterranean cultural traditions promote later home-leaving, with many young adults staying into their thirties.

Residential independence rises steadily with age; by the early thirties, 90 percent of U.S. young adults live on their own (U.S. Census Bureau, 2015a). Still, the percentage of U.S. young adults residing with parents is higher today than at any time in the past 60 years. Major contributing factors include reduced employment opportunities in the aftermath of the economic recession of 2007 to 2009 and postponement of committed romantic relationships and marriage (Pew Research Center, 2016a). As young people encounter unexpected twists and turns on the road to independence, the parental home offers a safety net and base of operations for launching adult life.

The extent to which young people live on their own before marriage varies with SES and ethnicity. Those who have a bachelor's degree and are employed are more likely to establish their own residence. Among African-American, Hispanic, and Native-American groups, poverty and a cultural tradition of extended-family living lead to markedly lower rates of leaving home, even among young people in college or working (Fingerman et al., 2015; Pew Research Center, 2016a). Unmarried Asian young adults also tend to live with their parents. But the longer Asian families have lived in the United States, where they are exposed to individualistic values, the more likely young people are to move out before marriage (Lou, Lalonde, & Giguère, 2012).

Parents of young adults living at home are usually highly committed to helping their children move into adult roles. Many provide wide-ranging assistance—not just financial support, but material resources, advice, companionship, and emotional support as well. A survey of a large sample of U.S. parents diverse in SES and ethnicity and their adult children revealed that parents gave more to those with greater needs (because of problems or younger age) and to those they perceived as more successful in education and career progress. Furthermore, most parents and young-adult children judged the amount of parental support to be appropriate, though a sizable minority viewed intense support (provided several times a week) as excessive (Fingerman et al., 2009, 2012c). Nevertheless, children receiving intense support adjusted especially well, expressing firmer goals and greater life

satisfaction—perhaps because the intense support matched their needs and they used it to advance their independence.

Still, in homes where parents and young adults live together, conflict over personal and moral values related to the young person's future tends to rise (Rodríguez & López, 2011). But when young adults feel securely attached to parents and well-prepared for independence, departure from the home is linked to more satisfying parent-child interaction and successful transition to adult roles, even among ethnic minorities that strongly emphasize family loyalty and obligations (Smetana, Metzger, & Campione-Barr, 2004; Whiteman, McHale, & Crouter, 2010). And regardless of living arrangements, young people doing well often have close, enjoyable relationships with their parents, who offer help because they see it as key to their child's future success (Fingerman et al., 2012b).

In contrast, resistantly attached young adults generally have difficulty with healthy separation. They often remain in the parental home for an extended time, and after leaving, they report greater parental contact than their agemates do (Seiffge-Krenke, 2006). Although avoidantly attached young people appear to adjust well to leaving home, they sometimes describe themselves as more self-sufficient than they actually are (Bernier, Larose, & Whipple, 2005; Seiffge-Krenke, 2013). They tend to be less well-adjusted than their securely attached counterparts.

Finally, leaving home very early can contribute to long-term disadvantage because it is associated with lack of parental financial and emotional support, job seeking rather than education, and earlier childbearing. Not surprisingly, U.S. non-college-bound youths who move out in their late teens tend to have less successful educational, marriage, and work lives. U.S. poverty-stricken young people are more likely than their nonpoor counterparts to leave home by age 18 (Berzin & De Marco, 2010). But if still at home beyond that age, they are less likely to move out well into their thirties—a trend that may reflect the steep challenges they face in attaining self-sufficiency and exiting poverty.

## Joining of Families in Marriage

The average age of first marriage in the United States has risen from about 20 for women and 23 for men in 1960 to 27 for women and 29 for men today. Consequently, just 16 percent of contemporary U.S. 18- to 29-year-olds are married, compared to 60 percent a half-century ago (Gallup, 2015b; U.S. Census Bureau, 2016b). Postponement of marriage is even more marked in Western Europe—to the early thirties.

The number of first and second marriages has declined over the last few decades as more people stay single, cohabit, or do not remarry after divorce. In 1960, 85 percent of Americans had been married at least once; today, the figure is 70 percent. At present, 49 percent of U.S. adults, slightly less than half, live together as married couples (U.S. Census Bureau, 2015a). Nevertheless, marriage remains a central life goal for young people (Pew Research Center, 2013a). Irrespective of SES and ethnicity, most U.S. unmarried young adults say they want to marry and have children.

Same-sex marriages are recognized nationwide in 20 nations: Argentina, Belgium, Brazil, Canada, Colombia, Denmark, France, Iceland, Ireland, Luxembourg, the Netherlands, New Zealand, Norway, Portugal, South Africa, Spain, Sweden, Uruguay, the United Kingdom (except for Northern Ireland), and the United States. Because legalization is recent, research on same-sex couples in the context of marriage is scant. But so far, evidence suggests that the same factors contribute to happiness in same-sex as in other-sex marriages. And both sexual majority and minority couples perceive marriage as important for the same reasons: because it confers public legitimacy to the relationship, demonstrates commitment, and offers financial and legal benefits (Haas & Whitton, 2015).

Marriage is more than the joining of two individuals. It also requires that two systems—the spouses' families—adapt and overlap to create a new subsystem. Consequently, marriage presents complex challenges. This is especially so today because husband–wife roles are only gradually moving toward true partnership—educationally, occupationally, and in emotional connectedness. Among same-sex couples, acceptance of the relationship by parents, inclusion of the partner in family events, and living in a supportive community where they can be open about their bond benefit relationship satisfaction and durability (Rith & Diamond, 2013).

**Marital Roles.** Their honeymoon over, Sharese and Ernie turned to a multitude of issues they had previously decided individually or their families of origin had prescribed—from everyday matters (when and how to eat, sleep, talk, work, relax, have sex, and spend money) to family traditions and rituals (which to retain, which to work out for themselves). And as they related to their social world as a couple, they modified relationships with parents, siblings, extended family, friends, and co-workers.

Contemporary alterations in the context of marriage, including changing gender roles and living farther from family members, mean that couples must work harder than in the past to define their relationships. Although partners are usually similar in religious and ethnic background, “mixed” marriages are increasingly common today. Among new marriages in the United States, 12 percent are between partners of a different race, double the rate in 1980 (Pew Research Center, 2015d). Because of increased opportunities for interracial contact in colleges, workplaces, and neighborhoods and more positive attitudes toward intermarriage, highly educated young adults are more likely than their less educated counterparts to marry partners of another race or ethnicity (Qian & Lichter, 2011). Nevertheless, couples whose backgrounds differ face extra challenges in transitioning to married life.

Because many couples live together beforehand, marriage has become less of a turning point in the family life cycle. Still, defining marital roles can be difficult. Age of marriage is the most consistent predictor of marital stability. Young people who marry in their teens to mid-twenties are more likely to divorce than those who marry later (Lehrer & Chen, 2011; Røsand et al., 2014). Most of those who marry early have not developed a secure identity or sufficient independence to form a mature

marital bond. Furthermore, early marriage is associated with low education and income—factors strongly linked to marital breakup (see page 353 in Chapter 10).

Despite progress in the area of women's rights, **traditional marriages**, involving a clear division of roles—husband as head of household responsible for family economic well-being, wife as caregiver and homemaker—still exist in Western nations. In recent decades, however, these marriages have changed, with many women who focused on motherhood while their children were young returning to the work force later. In **egalitarian marriages**, partners relate as equals, sharing power and authority. Both try to balance the time and energy they devote to their occupations, their children, and their relationship. Most well-educated, career-oriented women expect this form of marriage.

In Western nations, men in dual-earner marriages participate much more in child care than in the past, although on average they put in just 60 percent of weekly hours that mothers do (see pages 202–203 in Chapter 6). Similarly, recent surveys indicate women in the United States and European nations spend, on average, nearly twice as much time as men on housework (Pew Research Center, 2015e; Sayer, 2010).

But wide variations exist. In an investigation of over 7,500 European men and women who were married, cohabiting, or in civil unions, researchers gathered information on housework hours and gender-role attitudes. More egalitarian attitudes were strongly associated with women doing less housework (Treas & Tai, 2016). As Figure 14.3 shows, women's weekly housework hours ranged from a low of 11 to 13 in Norway, Finland, Sweden,

©GERI ENGBERG/THE IMAGE WORKS

A father braids his daughter's hair. In Western nations, men in dual-earner marriages participate much more in child care than in the past, although they still contribute far less than women do.

**FIGURE 14.3** Women's and men's housework hours in European nations varying in gender-role attitudes. When over 7,500 men and women in European countries reported on housework hours and gender-role attitudes, women's weekly time devoted to housework was greatly reduced in countries with more egalitarian attitudes. Across all countries, women devoted substantially more time to housework than did men. (From J. Treas & T. Tai, 2016, "Gender Inequality in Housework Across 20 European Nations: Lessons from Gender Stratification Theories," *Sex Roles*, 74, p. 502. Adapted with permission.)

and Iceland (Nordic nations that highly value gender equality) to a high of 24 to 26 in Poland, Lithuania, Croatia, and Slovenia (Eastern European countries more traditional in gender-role attitudes). Men's housework hours, however, did not rise in gender-egalitarian countries to compensate for women's reduced hours, and across all nations most home labor fell to women.

**TABLE 14.1**  
Factors Related to Marital Satisfaction

FACTOR	HAPPY MARRIAGE	UNHAPPY MARRIAGE
Backgrounds	Partners similar in SES, education, religion, and age	Partners very different in SES, education, religion, and age
Age at marriage	After mid-20s	Before mid-20s
Timing of first pregnancy	After first year of marriage	Before or within first year of marriage
Relationship to extended family	Warm and positive	Negative; wish to maintain distance
Marital patterns in extended family	Stable	Unstable; frequent separations and divorces
Financial and employment status	Secure	Insecure
Family responsibilities	Shared; perception of fairness	Largely the woman's responsibility; perception of unfairness
Personality characteristics and behavior	Emotionally positive; common interests; good conflict-resolution skills	Emotionally negative and impulsive; lack of common interests; poor conflict-resolution skills

Note: The more factors present, the greater the likelihood of marital happiness or unhappiness.

Sources: Diamond, Fagundes, & Butterworth, 2010; Gere et al., 2011.

Research in North America and Europe confirms that women's housework hours decline modestly as their employment hours and income increase (Cooke, 2010; Treas & Tai, 2016; Van der Lippe, 2010). Employed women's reduced time doing housework is likely made possible by either purchase of time-saving services (cleaning help, prepackaged meals) or greater tolerance for unkempt homes, or both. Perhaps women continue to do the lion's share of housework because their paid work is viewed as secondary to their husband's, regardless of how much they earn. And men's greater investment in household tasks in certain Eastern European countries (Latvia, Poland, Slovakia) may largely stem from lower family incomes and poorer quality housing than elsewhere. These factors require men to invest more in household labor, especially when their partners are employed.

In the United States, African-American and European-American men devote more time to housework than Asian and Hispanic men (Wight, Bianchi, & Hunt, 2012). Although gender-role attitudes may explain these variations, men are substantially less involved than women across all ethnic groups.

Finally, although a common assumption is that among same-sex couples, one partner assumes a traditionally "male" and the other a "female" role, this is rarely so. Rather egalitarian relationships, with equal sharing of authority and household tasks, are more common in same-sex than in other-sex relationships (Patterson, 2013). In sum, in heterosexual marriages, true equality is still rare, and couples who strive for it usually attain a form of marriage in between traditional and egalitarian.

**Marital Satisfaction.** Despite its rocky beginnings, Sharee and Ernie's marriage grew to be especially happy. In contrast, Christy and Gary became increasingly discontented. What distinguishes satisfying marriages from less successful partnerships? Differences between these two couples mirror the findings of a large body of research on personal and contextual factors, summarized in Table 14.1.

## Social Issues: Health

### Partner Abuse

Violence in families is a widespread health and human rights issue, occurring in all cultures and SES groups. Often one form of domestic violence is linked to others. Consider Karen, whose husband, Mike, not only assaulted her physically and sexually but also abused her psychologically— isolating, humiliating, and demeaning her. Violent adults also break their partner’s favorite possessions, punch holes in walls, or throw objects. “It was a control thing,” Karen explained. “He complained that I wouldn’t always do what he wanted. I didn’t leave because I was sure he would come after me and get more violent.”

Partner abuse in which husbands are perpetrators and wives are physically injured is most likely to be reported to authorities. But in studies spanning many countries in which people are asked directly, rates of assault experienced by men and women are similar. Women victims are more often physically injured, but sex differences in severity of abuse are small (Dutton, 2012; Esquivel-Santoveña, Lambert, & Hamel, 2013). Partner abuse also occurs at similar rates in same-sex and other-sex relationships (Stiles-Shields & Carroll, 2015).

Although self-defense is a frequently reported cause of domestic assault by women, American men and women are equally likely to “strike first” (Dutton et al., 2015). “Getting my partner’s attention,” “gaining control,” and “expressing anger” are reasons that partners typically give for abusing each other.

#### Factors Related to Partner Abuse

In abusive relationships, dominance–submission sometimes proceeds from husband to wife, sometimes from wife to husband. In at least half of cases, both partners are violent (Bartholomew, Cobb, & Dutton, 2015). Roy’s and Pat’s relationship helps us understand how partner abuse escalates. Shortly after their wedding, Pat complained about the demands of Roy’s work and insisted that he come home early to spend time with her. When he resisted, she hurled epithets, threw objects, and slapped him. One evening, Roy became so angry at Pat’s hostilities that he smashed a dish against the wall, threw his wedding ring at her, and left the house. The next morning, Pat apologized and promised not to attack again. But her outbursts became more frequent and desperate.

These violence–remorse cycles, in which aggression escalates, characterize many abusive relationships. Why do they occur? Personality and developmental history, family circumstances, and cultural factors combine to make partner abuse more likely.

Many abusers are overly dependent on their spouses, as well as jealous, possessive, and controlling. For example, the thought of Karen ever leaving induced such high anxiety in Mike that he monitored all her activities. Depression, anxiety, and low self-esteem also characterize abusers. And because they have great difficulty managing anger, trivial events—such as an unwashed shirt or a late meal—can trigger abusive episodes. When asked to explain their offenses, they attribute greater blame to their partner than to themselves (Henning, Jones, & Holdford, 2005).

A substantial proportion of spouse abusers grew up in homes where parents engaged in hostile interactions, used coercive discipline, and were abusive toward their children (Ehrensaft, 2009). Perhaps this explains why violent delinquency in adolescence also predicts partner abuse (Charles et al., 2011). Adults with childhood exposure to domestic

Christy and Gary had children early and struggled financially. Gary’s negative, critical personality led him to get along poorly with Christy’s parents and to feel threatened when he and Christy disagreed. Christy tried to offer Gary encouragement and support, but her own needs for nurturance and individuality were not being met. Gary was uncomfortable with Christy’s career aspirations. As she came closer to attaining them, the couple grew further apart. In contrast, Sharese and Ernie married later, after their educations were complete. They postponed having children until their careers were under way and they had built a sense of togetherness that allowed each to thrive as an individual. Patience, caring, common values and interests, humor, affection, sharing of personal experiences through conversation, cooperating in household responsibilities, and good conflict-resolution skills contributed to their compatibility.

Overall, men report feeling slightly happier with their marriages than women do, but the difference is largely limited to couples in marital therapy (Jackson et al., 2014). When a marriage is distressed, women are more likely to express dissatisfaction and seek professional help. Women feel particularly

dissatisfied with marriage when their husbands disagree with them about the extent to which household tasks should be shared and when conflict between the demands of family and work feels overwhelming. Role overload, however, is also linked to men’s marital dissatisfaction (Minnotte, Minnotte, & Bonstrom, 2015; Ogolsky, Dennison, & Monk, 2014). Research in both Western and non-Western industrialized nations reveals that equal power in the relationship and sharing of family responsibilities usually enhance both partners’ satisfaction, largely by strengthening marital harmony (Amato & Booth, 1995; Xu & Lai, 2004).

Of course, from time to time, individuals are bound to say or do something upsetting to their partner. When this happens, the partner’s attributions, or explanations for the behavior, make a difference. For example, a wife who interprets her husband’s critical remark about her weight as unintentional (“He just isn’t aware I’m sensitive about that”) is far more likely to express both current and long-term marital satisfaction than a wife who views such comments as malicious (“He’s trying to hurt my feelings”) (Barelds & Dijkstra, 2011; Fincham & Bradbury, 2004).

violence are not doomed to repeat it. But their parents provided them with negative expectations and behaviors that they often transfer to their close relationships. Stressful life events, such as job loss or financial difficulties, increase the likelihood of partner abuse. Because of widespread poverty, rates of abuse are elevated among African Americans and Native Americans (Black et al., 2011). Alcohol abuse is another related factor.

At a societal level, cultural norms that endorse male dominance and female submissiveness promote partner abuse (Esquivel-Santoveña, Lambert, & Hamel, 2013). In developing countries with widespread poverty that also sanction gender inequality, partner violence against women is especially high, affecting nearly half or more of the female population.

Victims are chronically anxious and depressed and experience frequent panic attacks (Warshaw, Brashler, & Gil, 2009). Why don't they simply leave these destructive relationships? A variety of situational factors discourage them from doing so. A victimized wife may depend on her husband's earning power or fear even worse harm to herself or her children. Extreme assaults, including homicide, tend to occur after partner separation (Duxbury, 2014). And victims of both

sexes, but especially men, are deterred by the embarrassment of going to the police. Also, victims may falsely believe that their partner will change.

### Intervention and Treatment

Community services available to battered women include crisis telephone lines that provide anonymous counseling and social support and shelters that offer safety and treatment (see page 454). Because many women return to their abusive partners several times before making their final move, community agencies usually offer therapy to perpetrators. Most rely on several months to a year of group sessions that confront rigid gender stereotyping; teach communication, problem solving, and anger control; and use social support to motivate behavior change (Hamel, 2014).

Although existing treatments are better than none, most are not effective at dealing with relationship difficulties or alcohol abuse. Consequently, many treated perpetrators

© KUMAR SRISKANDAN/ALAMY

Although partner abuse in which husbands physically harm their wives is most likely to be reported, wives assault their husbands at similar rates. Abusers' emotional problems include great difficulty managing anger.

repeat their violent behavior with the same or a new partner (Hamberger et al., 2009). At present, few interventions acknowledge that men also are victims. Yet ignoring their needs perpetuates domestic violence. When victims do not want to separate from a violent partner, a whole-family treatment approach that focuses on changing partner interaction and reducing high life stress is crucial.

In fact, partners who hold overly positive (but still realistic) biases concerning each other's attributes are happier with their relationships (Claxton et al., 2011). As they turn to each other for feedback about themselves, these "positive illusions" enhance self-esteem and psychological well-being. And over time, positive illusions favorably influence behavior, as partners modify their actions to bring them closer to their partner's generous perceptions.

In contrast, people who feel devalued by their partner tend to react with anxiety and insecurity—more so when they are low in self-esteem, which heightens fear of rejection. To protect themselves, they often mete out criticism and contempt in kind, setting in motion hostile, defensive exchanges that create the very rejection they fear (Murray, 2008). Alternatively, individuals may disengage emotionally, suppressing negative feelings so as not to poison the relationship (Driver et al., 2012). In the process, shared positive emotion also declines, and intimacy erodes.

At their worst, marital relationships can become contexts for intense opposition, dominance–submission, and emotional and physical violence. As the Social Issues: Health box above explains,

although women are more often targets of severe partner abuse, both men and women play both roles: perpetrator and victim.

High school and college courses in family life education can promote better mate selection and teach communication skills that contribute to gratifying romantic partnerships and marriages. And counseling aimed at helping couples listen to each other with understanding and empathy, focus on positive traits and memories, and use effective conflict-resolution strategies can cultivate the self-esteem, affection, and respect needed for the relationship to be resilient and enduring (Gottman, 2011).

## Parenthood

In the past, having children was, for many adults, a biological given or a compelling social expectation. Today, in Western industrialized nations, it is a matter of true individual choice. Effective birth control techniques enable adults to avoid having children in most instances. And changing cultural values allow people to remain childless with far less fear of social criticism

and rejection than a generation or two ago. Nevertheless, the 6 percent of American 18- to 40-year-olds who currently say they do not want children is just slightly higher than the 5 percent who said so a quarter century ago (Gallup, 2013).

Among U.S. adults age 40 and older, 85 percent of women and 76 percent of men are parents (U.S. Census Bureau, 2015b). At the same time, increasing numbers of young adults in industrialized nations are delaying parenthood or not having children. Consistent with this trend and with the decision of most mothers to divide their energies between family and work, family size has declined to an all-time low. In 1950, the average number of children per woman was 3.1; currently, it is 1.9 in the United States and Sweden, 1.8 in the United Kingdom, 1.6 in Canada, and 1.4 in Germany, Italy, and Japan (World Bank, 2016). Nevertheless, the vast majority of married people continue to embrace parenthood as one of life's most meaningful experiences. Why do they do so, and how do the challenges of child rearing affect the adult life course?

**The Decision to Have Children.** The choice of parenthood is affected by a complex array of factors, including financial circumstances, personal and religious values, career goals, health conditions, and availability of supportive government and workplace family policies. Women with traditional gender identities usually decide to have children. Those in high-status, demanding careers less often choose parenthood and, when they do, more often delay it than women with less consuming jobs. Parenthood typically reduces work hours and slows career progress among career-oriented women but has no impact on men (Abele, 2014; Abele & Spurk, 2011). Professional women often consider these consequences in decision making about parenthood.

Besides these influences, a vital personal factor called child-bearing motivations—each person's disposition to respond positively or negatively to the idea of parenthood—affects the decision to have children. In Western nations, these motivations have changed over time, increasingly emphasizing individual fulfillment and de-emphasizing obligation to society (Frejka et al., 2008).

When Americans and Europeans are asked about their desire to have children, they mention a variety of advantages and disadvantages. Although some ethnic and regional differences exist, in all groups highly rated reasons for having children include personal rewards—for example, the warm, affectionate relationship and opportunities for care and teaching that children provide. Also frequently mentioned are social returns, such as affirmation of one's adult status and children as a source of caregiving in later life (Guedes et al., 2013). Less important, but still mentioned, is a sense of future continuity—having someone carry on after one's own death. And occasionally, couples look to parenthood as a gratifying opportunity to share in a challenging but important life task and to deepen their relationship.

Most adults also realize that having children means years of extra burdens and responsibilities. Among disadvantages, they most often cite concerns about role overload, doubts about their own readiness for parenthood, and worries about bringing up

children in a troubled world. The financial strains of child rearing follow close behind. According to a conservative estimate, today's new parents in the United States will spend about \$300,000 to rear a child from birth to age 18, and many will incur substantial additional expense for higher education and financial dependency during emerging adulthood (U.S. Department of Agriculture, 2014).

Greater freedom to choose whether and when to have children makes contemporary family planning more challenging as well as intentional than it was in the past. Still, about 35 percent of U.S. births are the result of unintended pregnancies, with most born to low-income, less-educated mothers (Guttmacher Institute, 2013). Opportunities to explore childbearing motivations in high school, college, and community-based health education classes and through family-planning counseling might encourage more adults to make informed and personally meaningful decisions—a trend that would increase the chances that they would have children when ready and find parenting an enriching experience.

**Transition to Parenthood.** The early weeks after a baby enters the family are full of profound changes: constant caregiving, added financial responsibilities, and less time for the couple's relationship. In response, gender roles of husband and wife usually become more traditional—even for couples like Sharese and Ernie who are strongly committed to gender equality (Katz-Wise, Priess, & Hyde, 2010; Yavorsky, Dush, & Schoppe-Sullivan, 2015).

**First and Second Births.** For most new parents, the arrival of a baby—though often followed by mild declines in relationship and overall life satisfaction—does not cause significant marital strain (Doss et al., 2009; Lawrence et al., 2008; Luhmann et al., 2012). Marriages that are gratifying and supportive tend to remain so. But troubled marriages usually become even more distressed after childbirth (Houts et al., 2008; Kluwer & Johnson, 2007). And when expectant mothers anticipate lack of partner support in parenting, their prediction generally becomes reality, yielding an especially difficult post-birth adjustment (Driver et al., 2012; McHale & Rotman, 2007).

In dual-earner marriages, the larger the difference in men's and women's caregiving responsibilities, the greater the decline in marital satisfaction after childbirth, especially for women—with negative consequences for parent–infant interaction. In contrast, sharing caregiving predicts greater parental happiness and sensitivity to the baby (McHale et al., 2004; Moller, Hwang, & Wickberg, 2008). An exception exists, however, for employed lower-SES women who endorse traditional gender roles. When their husbands take on considerable child-care responsibilities, these mothers tend to report more distress, perhaps because of disappointment at being unable to fulfill their desire to do most of the caregiving (Goldberg & Perry-Jenkins, 2003).

Postponing childbearing until the late twenties or thirties, as more couples do today, eases the transition to parenthood. Waiting permits couples to pursue occupational goals, gain life experience, and strengthen their relationship. Under these circumstances, men are more enthusiastic about becoming fathers

Couples are increasingly postponing childbearing until their late twenties or thirties. This later transition to parenthood gives them time to pursue occupational goals, gain life experience, and strengthen their relationship.

and therefore more willing to participate. And women whose careers are well under way and whose marriages are happy are more likely to encourage their husbands to share housework and child care, which fosters fathers' involvement (Lee & Doherty, 2007; Schoppe-Sullivan et al., 2008).

A second birth typically requires that fathers take an even more active role in parenting—by caring for the firstborn while the mother is recuperating and by sharing in the high demands of tending to both a baby and a young child. Consequently, well-functioning families with a newborn second child typically pull back from the traditional division of responsibilities that occurred after the first birth. Fathers' willingness to place greater emphasis on the parenting role is strongly linked to mothers' adjustment after the arrival of a second baby (Stewart, 1990). And the support and encouragement of family, friends, and spouse are crucial for fathers' well-being.

**Interventions.** Couples' groups led by counselors are effective in easing the transition to parenthood (Gottman, Gottman, & Shapiro, 2010). Therapists report that many couples know little about caring for infants, perhaps because they grew up in small families where they had few sibling caregiving responsibilities. They are also unaware of the potential impact of a new baby on their relationship.

In one program, first-time expectant couples gathered once a week for 4 to 6 months to discuss their dreams for the family and changes in relationships sparked by the baby's arrival. Eighteen months after the program ended, participating fathers described themselves as more involved with their child than did fathers in a no-intervention condition. Perhaps because of fathers' caregiving assistance, participating mothers maintained their

prebirth satisfaction with family and work roles. Three years after the birth, the marriages of participating couples were intact and just as happy as they had been before parenthood. In contrast, 15 percent of couples receiving no intervention had divorced (Cowan & Cowan, 1997; Schulz, Cowan, & Cowan, 2006).

High-risk parents struggling with poverty or the birth of a child with disabilities need more intensive interventions aimed at enhancing social support and parenting skills. Many low-income single mothers benefit from programs that focus on sustaining the father's involvement (Jones, Charles, & Benson, 2013).

Generous, paid employment leave—widely available in industrialized nations but not in the United States—is crucial for parents of newborns. But as we saw in Chapter 3, financial pressures mean that many new mothers who are eligible for unpaid work leave take far less than they are guaranteed, while new fathers take little or none. When favorable workplace policies exist and parents take advantage of them, couples are more likely to support each other and experience family life as gratifying (Feldman, Sussman, & Zigler, 2004). As a result, the stress caused by the birth of a baby stays at manageable levels.

**Families with Young Children.** A year after the birth of their first child, a friend asked Sharese and Ernie how they liked parenthood: “Is it a joy, a dilemma, a stressful experience—how would you describe it?”

Chuckling, Sharese and Ernie responded in unison, “All of the above!”

In today's complex world, men and women are less certain about how to rear children than in previous generations. Clarifying child-rearing values and implementing them in warm, involved, and appropriately demanding ways are crucial for the welfare of the next generation and society. Yet cultures do not always place a high priority on parenting, as indicated by lack of societal supports for children and families (see Chapter 2, page 64). Furthermore, changing family forms mean that the lives of today's parents differ substantially from those of past generations.

In previous chapters, we discussed a wide variety of influences on child-rearing styles, including personal characteristics of children and parents, SES, and ethnicity. The couple's relationship is also vital. Parents who engage in effective coparenting, collaborating in parenting roles, are more likely to feel competent as parents, use effective child-rearing practices, and have children who are developing well. And they also gain in marital satisfaction (see page 57).

For employed parents, major struggles include finding good child care and, when their child is ill or otherwise in need of emergency care, taking time off from work or making other urgent arrangements. The younger the child, the greater parents' sense of risk and difficulty—especially low-income parents, who must work longer hours to pay bills; who often, in the United States, have no workplace benefits (health insurance or paid sick leave); who typically cannot afford the cost of child care; and who experience more immediate concerns about their children's safety (Nomaguchi & Brown, 2011). When competent, convenient child care is not available, the woman usually faces added pressures. She must either curtail or give up her work or endure

unhappy children, missed workdays, and constant searches for new arrangements.

Despite its challenges, rearing young children is a powerful source of adult development. Parents report that it expands their emotional capacities, makes life more meaningful, and enhances psychological well-being (Nelson et al., 2013; Nomaguchi & Milkie, 2003). Ernie remarked that through sharing in child rearing, he felt “rounded out” as a person. Other involved parents say that parenthood helped them tune in to others’ feelings and needs, required that they become more tolerant, self-confident, and responsible, and broadened their extended family, friendship, and community ties. In a survey of a large, nationally representative sample of U.S. fathers, paternal history of engagement with children predicted greater community service and assistance of extended family members in middle adulthood (Eggebeen, Dew, & Knoester, 2010).

**Families with Adolescents.** Adolescence brings sharp changes in parental roles. In Chapters 11 and 12, we noted that parents must establish a revised relationship with their adolescent children—blending guidance with freedom and gradually loosening control. As adolescents gain in autonomy and explore values and goals in their search for identity, parents often complain that their teenager is too focused on peers and no longer cares about being with the family. Heightened parent-child bickering over everyday issues takes a toll, especially on mothers, who do most of the negotiating with teenagers.

Overall, children seem to navigate the challenges of adolescence more easily than parents, many of whom report a dip in marital and life satisfaction (Cui & Donnellan, 2009). More people seek family therapy during this phase of the family life cycle than during any other.

**Parenting Education.** In the past, family life changed little from one generation to the next, and adults learned what they needed to know about parenting through modeling and direct experience. Today’s world confronts adults with a host of factors that impinge on their ability to succeed as parents.

Contemporary parents eagerly seek information on child rearing. In addition to popular parenting books, magazines, and websites, new mothers access knowledge about parenting through social media. They also reach out to family members and networks of other women for assistance. Fathers, by contrast, less often have social networks through which they can learn about child rearing. Consequently, they frequently turn to their partner to figure out how to relate to their child, especially if they have a close, confiding marriage (McHale, Kuersten-Hogan, & Rao, 2004; Radey & Randolph, 2009). Recall from Chapter 6 that marital harmony fosters both parents’ positive engagement with babies but is especially important for fathers.

Parent education courses exist to help parents clarify child-rearing values, improve family communication, understand how children develop, and apply more effective parenting strategies. A variety of programs yield positive outcomes, including enhanced knowledge of effective parenting practices, improved parent-child interaction, heightened awareness by parents of

Fathers are less likely than mothers to have social networks they can access to learn about child rearing. This young father and his son interact with an older neighbor, who models effective parenting.

their role as educators of their children, and gains in psychological well-being (Bennett et al., 2013; Smith, Perou, & Lesesne, 2002). Another benefit is social support—opportunities to discuss concerns with experts and other dedicated parents, who share the view that no job is more important to the future of society than child rearing.

## Ask yourself

**CONNECT** What aspects of adolescent development make rearing teenagers stressful for parents, leading to a dip in marital and life satisfaction? (See Chapter 11, page 376, and Chapter 12, pages 420–422.)

**APPLY** After her wedding, Sharese was convinced she had made a mistake. Cite factors that sustained her marriage and led it to become highly satisfying.

**REFLECT** Do you live with your parents or on your own? Describe factors that contributed to your current living arrangements. How would you characterize the quality of your relationship with your parents? Do your responses match the findings of research?

## The Diversity of Adult Lifestyles

**14.8** Discuss the diversity of adult lifestyles, focusing on singlehood, cohabitation, and childlessness.

**14.9** Cite factors that contribute to high rates of divorce and remarriage.

**14.10** Discuss challenges associated with varied styles of parenthood, including stepparents, never-married parents, and gay and lesbian parents.

The current array of adult lifestyles dates back to the 1960s, when young people began to question the conventional wisdom of previous generations and to ask, “How can I find happiness? What kinds of commitments should I make to live a full and

rewarding life?” As the public became more accepting of diverse lifestyles, choices such as staying single, cohabiting, remaining childless, and divorcing seemed more available.

Today, nontraditional family options have penetrated the American mainstream. Many adults experience not just one but several. As we will see, some adults make a deliberate decision to adopt a lifestyle, whereas others drift into it. The lifestyle may be culturally imposed, as is the case for cohabiting same-sex couples who live in countries or regions where they cannot marry legally. Or people may choose a certain lifestyle because they feel pushed away from another, such as a marriage gone sour. In sum, the adoption of a lifestyle can be within or beyond the person’s control.

## Singlehood

On finishing her education, Heather joined the Peace Corps and spent four years in Ghana. Though open to a long-term relationship, she had only fleeting romances. After she returned to the United States, she went from one temporary job to another until, at age 30, she finally secured steady employment in a large international travel company as a tour director. A few years later, she advanced into a management position. At age 35, over lunch with Sharese, she reflected on her life: “I was open to marriage, but after I got my career going, it would have interfered. Now I’m so used to independence that I question whether I could adjust to living with another person. I like being able to pick up and go where I want, when I want, without having to ask anyone or think about caring for anyone. But there’s a trade-off: I sleep alone, eat most of my meals alone, and spend a lot of my leisure time alone.”

*Singlehood*—not living with an intimate partner—has increased in recent years, especially among young adults. For example, the rate of never-married Americans age 25 and older has more than doubled since 1960, to 23 percent of men and 17 percent of women. Today, more people marry later or not at all, and divorce has added to the numbers of single adults—slightly more than half when adults of all ages are considered. In view of these trends, it is likely that most Americans will spend a substantial part of their adult lives single, and a growing minority—about 8 to 10 percent—will stay that way (Pew Research Center, 2014b).

Because they marry later, more young-adult men than women are single. But women are far more likely than men to remain single for many years or their entire life. With age, fewer men are available with characteristics that most women seek in a mate—the same age or older, equally or better educated, and professionally successful. In contrast, men can choose partners from a large pool of younger unmarried women. Because of the tendency for women to “marry up” and men to “marry down,” men with a high school diploma or less and highly educated women in prestigious careers are overrepresented among singles after age 30.

Ethnic differences also exist. For example, more than one-third of African Americans age 25 and older have never married, a figure more than double that of European Americans (Pew Research Center, 2014b). As we will see later, high unem-

ployment among black men interferes with marriage. Many African Americans eventually marry in their late thirties and forties, a period in which black and white marriage rates move closer together.

Singlehood can have a variety of meanings. At one extreme are people who choose it deliberately; at the other are those who see themselves as single because of circumstances beyond their control. Most, like Heather, are in the middle—adults who want to marry but made choices that took them in a different direction or say they have not found the right person. In interviews with never-married women, some said they focused on occupational goals instead of marriage (Baumbusch, 2004; Pew Research Center, 2014b). Others reported that they found singlehood preferable to their disappointing intimate relationships.

The most commonly mentioned advantages of singlehood are freedom and mobility. But singles also recognize drawbacks—loneliness, the dating grind, limited sexual and social life, reduced sense of security, and feelings of exclusion from the world of married couples. Single men have more physical and mental health problems than single women, who more easily come to terms with their lifestyle, in part because of the greater social support available to women through intimate same-sex friendships. But overall, people over age 35 who have always been single are content with their lives (DePaulo & Morris, 2005; Pinquart, 2003). Though not quite as happy as married people, they report feeling considerably happier than people recently widowed or divorced.

Nevertheless, many single people go through a stressful period in their early thirties, when most of their friends have married and they become increasingly mindful of their own departure from society’s marital social clock. Widespread veneration of marriage, along with negative stereotyping of singles as socially immature and self-centered, contributes (Morris et al., 2008). The mid-thirties is another trying time, as the biological deadline for pregnancy approaches. Interviews with 28- to 34-year-old single women revealed that they were acutely aware of pressures from family members, the shrinking pool of eligible

Compared with single men, single women more easily come to terms with their lifestyle, in part because of the greater social support available to women through intimate same-sex friendships.

men, the risks of later childbearing, and a sense of being different (Sharp & Ganong, 2011). A few decide to become parents through artificial insemination or a love affair. And an increasing number are adopting, often from overseas countries.

## Cohabitation

**Cohabitation** refers to the lifestyle of unmarried couples who have a sexually intimate relationship and who share a residence. Until the 1960s, cohabitation in Western nations was largely limited to low-SES adults. Since then, it has increased in all groups, with an especially dramatic rise among well-educated, economically advantaged young people. Today's young adults are much more likely than those of a generation ago to form their first conjugal union through cohabitation. Among U.S. young people, cohabitation is now the preferred mode of entry into an intimate partnership, chosen by over 70 percent of couples age 30 and younger (Copen, Daniels, & Mosher, 2013). Cohabitation rates are even higher among adults with failed marriages; about one-third of these households include children.

For some couples, cohabitation serves as *preparation for marriage*—a time to test the relationship and get used to living together. For many others, it is an *alternative to marriage*, offering the rewards of sexual intimacy and companionship along with the possibility of easy departure if satisfaction declines. It is not surprising, then, that cohabiters vary greatly in the extent to which they share money and possessions and take responsibility for each other's children.

Although Americans have become increasingly favorable toward cohabitation, with more than 60 percent expressing approval, their attitudes are not as positive as those of Western Europeans. In the Netherlands, Norway, and Sweden, cohabitation is thoroughly integrated into society. Cohabitors have many of the same legal rights and responsibilities as married couples and express nearly the same level of commitment to each other (Daugherty & Copen, 2016; Perelli-Harris & Gassen, 2012). Whereas about 60 percent of American cohabiting unions break up within three years, only 6 to 16 percent dissolve in Western Europe (Guzzo, 2014; Kiernan, 2002). When they decide to marry, Dutch, Norwegian, and Swedish cohabiters more often do so to legalize their relationships, especially for the sake of children. American cohabiters typically marry to affirm their love and commitment—sentiments that Western Europeans attach to cohabitation.

As cohabitation has risen in acceptability in the United States, cohabiting relationships have become more prone to dissolution. Two decades ago, U.S. cohabiters who were engaged were more likely than their non-engaged counterparts to stay together and transition to lasting marriages. But today, the majority of both types of cohabiting relationships dissolve at a similarly high rate (60 percent) and less often lead to marriage (Guzzo, 2014). Furthermore, engagement at the start of cohabitation is declining while cohabitation is on the rise—trends suggesting that contemporary cohabitation is less often serving as preparation for marriage (Vespa, 2014). More U.S. young adult

Cohabitation is common throughout Western industrialized nations. As this cohabiting couple brings home a newly adopted dog, the longevity of their relationship will depend on how committed they are to each other.

cohabiters are entering these unions without expectations or plans to marry, perhaps motivated instead by a desire to increase the cost-effectiveness and convenience of life with their current romantic partner.

Furthermore, couples who do transition from cohabitation to marriage are at slightly greater risk of divorce than couples who marry directly, without cohabiting. But the difference is largely explained by the earlier age at which premarital cohabiters, compared with direct marriers, began living together (Kuperberg, 2014). Premarital cohabitation before age 25, like early marriage, is associated with reduced readiness to select a compatible partner and forge a committed romantic bond. Also, young premarital cohabiters are more likely than direct marriers to be non-college-educated, to come from single-parent families, to differ in age and background from their partner, and to have previously cohabited with a partner other than their spouse. Among couples in general, all these factors are linked to risk of divorce.

Lesbian and gay cohabiters are exceptions to the high risk for breakup just described. The legal right to marry, granted to same-sex couples throughout the United States in 2015, is so recent that many already viewed their cohabiting relationships as symbols of long-term commitment (Haas & Whitton, 2015). When marriage became broadly available, nearly 100,000 same-sex couples transitioned from cohabitation to marriage within the following four months, yielding an 8 percent marriage-rate gain (Gallup, 2015c). If this trend continues, perhaps marriage will supplant cohabitation as the more common relationship status among committed same-sex couples, as it is among committed heterosexual couples.

In sum, cohabitation combines the rewards of a close relationship with the opportunity to avoid legal marital obligations. But cohabiting couples can encounter difficulties precisely because they do not have these obligations. Disputes over property, money, rental contracts, and responsibility for children are the rule rather than the exception when unmarried couples split up.

## Childlessness

At work, Sharese got to know Beatrice and Daniel. Married for seven years and in their mid-thirties, they did not have children and were not planning any. To Sharese, their relationship seemed especially caring and affectionate. “At first, we were open to becoming parents,” Beatrice explained, “but eventually we decided to focus on our marriage.”

Childlessness among U.S. women in their mid-forties increased from 10 percent in 1975 to 20 percent in 2006, and then declined to 15 percent in 2014 (Pew Research Center, 2015b). Some people are *involuntarily childless* because they did not find a partner with whom to share parenthood or their efforts at fertility treatments did not succeed. Beatrice and Daniel are in another category—men and women who are *voluntarily childless*.

But voluntary childlessness is not always a permanent condition. A few people decide early that they do not want to be parents and stick to their plans. But most, like Beatrice and Daniel, make their decision after they are married and have developed a lifestyle they do not want to give up. Later, some change their minds. The voluntarily childless are usually highly educated, have prestigious occupations, are very committed to their work, and are less traditional in gender-role attitudes (Gold, 2012). At the same time, the recent decline in childlessness is largely due to more educated, career-focused women, who are more numerous than in the past, eventually opting for parenthood.

Negative stereotypes of nonparenthood—as a sign of self-indulgence and irresponsibility—have weakened in Western nations as people have become more accepting of diverse lifestyles (Dykstra & Hagestad, 2007). In line with this trend, voluntarily childless adults are just as content with their lives as parents who have warm relationships with their children. But adults who cannot overcome infertility are likely to be dissatisfied—some profoundly disappointed, others more ambivalent, depending on compensations in other areas of their lives (Letherby, 2002; Luk & Loke, 2015). Childlessness seems to interfere with adjustment and life satisfaction only when it is beyond a person’s control.

## Divorce and Remarriage

Divorce rates have declined over the past two decades, partly because of rising age at marriage, which is linked to greater financial stability and marital satisfaction. In addition, the increase in cohabitation has curtailed divorce: Many relationships that once would have been marriages now break up before marriage. Still, from 42 to 45 percent of U.S. marriages dissolve (U.S. Census Bureau, 2015b). Because most divorces occur within seven years of marriage, many involve young children. Divorces are also common during the transition to midlife, when people have adolescent children—a period (as noted earlier) of reduced marital satisfaction.

Nearly 60 percent of divorced adults remarry. But marital failure is even greater during the first few years of second

marriages—10 percent above that for first marriages. Afterward, the divorce rates for first and second marriages are similar (Lewis & Kreider, 2015).

**Factors Related to Divorce.** Why do so many marriages fail? As Christy and Gary’s divorce illustrates, the most obvious reason is a disrupted relationship. Christy and Gary did not argue more than Sharese and Ernie. But their problem-solving style was ineffective, and it weakened their attachment to each other. When Christy raised concerns, Gary reacted with contempt, defensiveness, and refusal to communicate. This demand–withdraw pattern is found in many partners who split up, with women more often insisting on change and men more often retreating. Another typical style involves little conflict (Gottman & Gottman, 2015). Rather, partners increasingly disengage emotionally from each other, leading separate lives because they have different expectations of family life and few shared interests, activities, or friends.

What problems underlie these maladaptive communication patterns? In a nine-year longitudinal study, researchers asked a nationally representative sample of 2,000 U.S. married people about relationship problems and followed up 3, 6, and 9 years later to find out who had separated or divorced (Amato & Rogers, 1997). Compared to men, women reported more problems, largely involving their emotions, such as anger and hurt feelings. Men seemed to have difficulty sensing their wife’s distress, which contributed to her view of the marriage as unhappy. Regardless of which spouse reported the problem or was judged responsible for it, the strongest predictors of divorce during the following decade were infidelity, spending money foolishly, drinking or using drugs, expressing jealousy, engaging in irritating habits, and moodiness.

Background factors that increase the chances of divorce are younger age at marriage, being previously divorced, and having parents who had divorced—all of which are linked to marital difficulties. For example, couples who married at younger ages are more likely to report infidelity and jealousy. And research conducted in diverse industrialized nations consistently confirms that parental divorce elevates risk of divorce in the next generation, in part because it promotes child adjustment problems and reduces commitment to the norm of lifelong marriage (Diekmann & Schmidheiny, 2013). As a result, when adult children marry, they are more likely to engage in inconsiderate behaviors and to have conflict-ridden relationships and less likely to try to work through these difficulties or (if they do try) to have the skills to do so. Marriage to a caring spouse from a stable family background reduces these negative outcomes.

Poorly educated, economically disadvantaged couples who suffer multiple life stresses are especially likely to split up (Lewis & Kreider, 2015). But Christy’s case represents another trend—elevated marital breakup among career-oriented, economically independent women whose education and income exceed their husband’s—an outcome explained by differing gender-role beliefs between the spouses. However, the tendency for these couples to divorce at higher rates is subsiding (Schwartz & Han,

FREDERICK BASS/GETTY IMAGES

An ineffective problem-solving style can lead to divorce. Partners who split up often follow a pattern in which one partner raises concerns, and the other reacts with contempt, defensiveness, and refusal to communicate.

2014). The likely reason is a cultural shift toward more egalitarian partnerships in contemporary marriages.

In addition to the factors just described, American individualism—which includes the belief that each person has the right to pursue self-expression and personal happiness—contributes to the unusually high U.S. divorce rate (see page 353 in Chapter 10) (Amato, 2014). When people are dissatisfied with their intimate relationship, the cultural value of individualism encourages moving on.

**Consequences of Divorce.** Divorce involves the loss of a way of life and therefore a part of the self sustained by that way of life. As a result, it provides opportunities for both positive and negative change. Immediately after separation, both men and women experience disrupted social networks, a decline in social support, and increased anxiety and depression (Braver & Lamb, 2013). For most, these reactions subside within two years. Non-working women who organized their identities around their husbands have an especially hard time. And some noncustodial fathers feel disoriented and rootless as a result of decreased contact with their children (Coleman, Ganong, & Leon, 2006). Others distract themselves with a frenzy of social activity.

Finding a new partner contributes most to the psychological well-being of divorced adults (Gustavson et al., 2014). But it is more crucial for men, who adjust less well than women to living on their own. Despite loneliness and a drop in income (see Chapter 10), women—especially those who were in very low-quality marriages—tend to bounce back more easily from divorce (Bourassa, Sbarra, & Whisman, 2015). Christy, for example, developed new friendships and a gratifying sense of self-reliance. However, a few women—especially those who are anxious and fearful, who remain strongly attached to their ex-spouses, or who lack education and job skills—experience a drop in self-esteem and persistent depression (Coleman, Ganong, & Leon, 2006). Job training, continued education, career advancement, and social support from family and friends play vital roles in the economic and psychological well-being of many divorced women.

**Remarriage.** On average, people remarry within four years of divorce, men somewhat faster than women. As noted earlier, remarriages are especially vulnerable to breakup, for several reasons. First, practical matters—financial security, help in rearing children, relief from loneliness, and social acceptance—figure more heavily into choice of a second-marriage partner than a first. As a result, remarried couples are more likely than first-marriage couples to differ in age, education level, ethnicity, religion, and other background factors. These conditions do not provide a sound footing for a lasting partnership. Second, some people transfer the negative patterns of interaction learned in their first marriage to the second. Third, people with a failed marriage behind them are even more likely to view divorce as an acceptable solution when marital difficulties resurface. Finally, remarried couples experience more stress from stepfamily situations (Coleman, Ganong, & Russell, 2013). As we will see, step-parent–stepchild ties are powerful predictors of marital happiness.

Blended families generally take 3 to 5 years to develop the connectedness and comfort of intact biological families. Family life education, couples counseling, and group therapy can help divorced and remarried adults adapt to the complexities of their new circumstances (Pryor, 2014).

## Varied Styles of Parenthood

Diverse family forms result in varied styles of parenthood. Each type of family—blended, never-married, gay or lesbian, among others—presents unique challenges to parenting competence and adult psychological well-being.

**Stepparents.** Whether stepchildren live in the household or visit only occasionally, stepparents are in a difficult position. Stepparents enter the family as outsiders and, too often, move into their new parental role too quickly. Lacking a warm attachment bond to build on, their discipline is usually ineffective. Stepparents frequently criticize the biological parent for being too lenient, while the biological parent may view the stepparent as too harsh (Ganong & Coleman, 2004). Compared with first-marriage parents, remarried parents typically report higher levels of tension and disagreement, most centering on child-rearing issues. When both adults have children from prior marriages, rather than only one, more opportunities for conflict exist and relationship quality tends to be poorer.

Stepmothers, particularly the 10 percent who live in the same residence as stepchildren, are especially likely to experience conflict. Those who have not previously been married and had children may have an idealized image of family life, which is quickly shattered. Expected to be in charge of family relationships, stepmothers quickly find that stepparent–stepchild ties do not develop instantly. After divorce, biological mothers are frequently jealous and uncooperative. Even when their husbands do not have custody, stepmothers feel stressed. As stepchildren go in and out of the nonresident home, stepmothers find life easier without uncooperative children and then may feel guilty about

their “unmaternal” feelings (Church, 2004; Pryor, 2014). A stepmother may eventually succeed in building a close parent–child bond, but her efforts are likely to meet with resistance in the short run.

Stepfathers with children of their own tend to establish positive bonds with stepchildren, especially stepsons, more readily, perhaps because they are experienced in building warm parent–child ties and feel less pressure than stepmothers to plunge into parenting (Ganong et al., 1999; van Eeden-Moorefield & Pasley, 2013). But stepfathers without biological children (like their stepmother counterparts) can have unrealistic expectations. Or their wives may push them into the father role, sparking negativity from children. After making several overtures that are ignored or rebuffed, these stepfathers frequently withdraw from parenting (Hetherington & Clingempeel, 1992).

In interviews in which young-adult stepchildren provided retrospective accounts of their stepparent relationships, the quality of these ties varied widely, from warm and loving, to ambivalent, to coexisting, to critical and rejecting. A caring relationship between remarried or cohabiting couples, sensitive relationship-building behaviors by the stepparent, cooperation from the biological parent, and supportive extended family members all affected the development of stepparent–stepchild ties. Over time, many couples built a coparenting partnership that improved interactions with stepchildren (Ganong, Coleman, & Jamison, 2011). But establishing stepparent–stepchild bonds is challenging, contributing to a higher divorce rate for remarried couples with stepchildren than for those without them.

**Never-Married Single Parents.** Over the past several decades, births to unmarried mothers in industrialized nations have increased dramatically. Today, about 40 percent of U.S. births are to single mothers, more than double the percentage in 1980. Whereas teenage parenthood has declined steadily since 1990 (see page 384 in Chapter 11), births to single adult women have increased, with a particularly sharp rise during the first decade of the twenty-first century (Hamilton et al., 2015).

A growing number of nonmarital births are planned and occur to cohabiting couples. But these relationships—common among young adults with low education—are often unstable (Cherlin, 2010; Gibson-Davis & Rackin, 2014). In addition, more than 12 percent of U.S. children live with a single parent who has never married and does not have a partner. Of these parents, about 90 percent are mothers, 10 percent fathers (Curtin, Ventura, & Martinez, 2014).

Single motherhood is especially prevalent among African-American young women, who are considerably more likely than white women to give birth outside of marriage and less likely to live with the baby’s father. As a result, more than half of births to black mothers in their twenties are to women without a partner, compared with about 14 percent of births to white women (Child Trends, 2015a; Hamilton et al., 2015). Job loss, persisting unemployment, and consequent inability of many black men to support a family have contributed to the number of African-American never-married, single-mother families.

Never-married African-American mothers tap the extended family, especially their own mothers and sometimes male relatives, for help in rearing their children (Anderson, 2012). Compared with their white counterparts, low-SES African-American women tend to marry later—within a decade after birth of the first child—but not necessarily to the child’s biological father (Dixon, 2009; Wu, Bumpass, & Musick, 2001).

Still, for low-SES women, never-married parenthood generally increases financial hardship; about half live in poverty (Mather, 2010). Nearly 50 percent of white mothers and 60 percent of black mothers have a second child while unmarried. And they are far less likely than divorced mothers to receive paternal child support payments, although child support enforcement both reduces financial stress and increases father involvement (Huang, 2006).

Many children in single-mother homes display adjustment problems associated with economic disadvantage (Lamb, 2012). Furthermore, children of never-married mothers who lack a father’s consistent warmth and involvement show less favorable cognitive development and engage in more antisocial behavior than children in low-SES, first-marriage families—problems that make life more difficult for mothers (Waldfogel, Craigie, & Brooks-Gunn, 2010). But marriage to the child’s biological father benefits children only when the father is a reliable source of economic and emotional support. For example, adolescents who feel close to their nonresident father fare better in school performance and emotional and social adjustment than do those in two-parent homes where a close father tie is lacking (Booth, Scott, & King, 2010).

Unfortunately, most unwed fathers—who usually have no more than a modest education and are doing poorly financially—gradually spend less and less time with their children (Lerman, 2010). Strengthening parenting skills, social support, education, and employment opportunities for low-SES parents would greatly enhance the well-being of unmarried mothers and their children.

**Lesbian and Gay Parents.** According to recent estimates, about 20 to 35 percent of lesbian couples and 5 to 15 percent of gay couples are parents, most through previous heterosexual marriages, some through adoption, and a growing number through reproductive technologies (Brewster, Tillman, & Jokinen-Gordon, 2014; Gates, 2013). In the past, because of laws assuming that gay men and lesbians could not be adequate parents, those who divorced a heterosexual partner lost custody of their children. Today, the majority of U.S. states hold that sexual orientation is irrelevant to custody or adoption—a change likely spurred by the increasing acceptance of same-sex marriage. Custody and adoption by same-sex couples are also legal in many other industrialized nations.

Most research on families headed by same-sex couples is limited to volunteer samples. Findings indicate that lesbian and gay parents are as committed to and effective at child rearing as heterosexual parents and sometimes more so (Bos, 2013). Also, whether born to or adopted by their parents or conceived through donor insemination, children in lesbian and gay families do not

© HERO IMAGES INC./ALAMY

Lesbian and gay parents are as committed to and effective at child rearing as heterosexual parents. Overall, families headed by same-sex couples can be distinguished from other families mainly by issues related to living in discriminatory contexts.

differ from the children of heterosexual parents in mental health, peer relations, gender-role behavior, or quality of life (Bos & Sandfort, 2010; Farr, Forssell, & Patterson, 2010; Goldberg, 2010; van Gelderen et al., 2012).

To surmount the potential bias associated with volunteer samples, some researchers take advantage of large, nationally representative data banks to study lesbian and gay families. Findings confirm that children with same-sex and other-sex parents develop similarly, and that children's adjustment is linked to factors other than parental sexual orientation (Moore & Stambolis-Ruhstorfer, 2013). For example, close parent-child relationships predict better peer relations and a reduction in adolescent delinquency, whereas family transitions (such as parental divorce or remarriage) predict academic difficulties, regardless of family form (Potter, 2012; Russell & Muraco, 2013).

The large majority of children of lesbian and gay parents identify as heterosexual (Patterson, 2013). But some evidence suggests that more adolescents from lesbian and gay families experiment for a time with partners of both sexes, perhaps as a result of being reared in families and communities especially tolerant of nonconformity and difference (Bos, van Balen, & van den Boom, 2004; Gartrell, Bos, & Goldberg, 2011).

When extended-family members withhold acceptance, lesbian and gay parents often build "families of choice" through friends, who assume the roles of relatives. Usually, however, parents of sexual minorities cannot endure a permanent rift (Fisher, Easterly, & Lazear, 2008). With time, extended family relationships become more positive and supportive.

A major concern of lesbian and gay parents is that their children will be stigmatized by their parents' sexual orientation. Peer teasing and disapproval are problems for some children of same-sex parents, but close parent-child relationships, supportive school environments, and connections with other lesbian and gay families protect children from the negative effects of these experiences (Bos, 2013). Overall, lesbian and gay families can be distinguished from other families mainly by issues related to living in discriminatory contexts.

## Ask yourself

**CONNECT** Return to Chapter 10, pages 353–356, and review the impact of divorce and remarriage on children and adolescents. How do those findings resemble outcomes for adults? What might account for the similarities?

**APPLY** After dating for three months, Wanda and Scott decided to live together. What questions would you ask Wanda and Scott to predict the likelihood that their cohabiting relationship will be gratifying and eventually transition to a lasting marriage?

**REFLECT** Do your own experiences or those of your friends match research findings on cohabitation, singlehood, never-married parents, or gay and lesbian parents? Select one instance and discuss.

## Career Development

**14.11** Discuss patterns of career development, and cite difficulties faced by women, ethnic minorities, and dual-earner couples.

Besides family life, vocational life is a vital domain of social development in early adulthood. After choosing an occupation, young people must learn how to perform its tasks well, get along with co-workers, respond to authority, and protect their own interests. When work experiences go well, adults develop new competencies, feel a sense of personal accomplishment, make new friends, and become financially independent and secure. And as we have seen, especially for women but also for men who support their partner's career development, aspirations and accomplishments in the workplace and the family are interwoven.

### Establishing a Career

Our discussion earlier in this chapter highlighted diverse paths and timetables for career development. Consider, once again, the wide variations among Sharese, Ernie, Christy, and Gary. Notice that Sharese and Christy, like many women, had *discontinuous* career paths—ones that were interrupted or deferred by child rearing and other family needs (Heppner & Jung, 2013; Huang & Sverke, 2007). Furthermore, not all people embark on the vocation of their dreams. For example, the economic recession of 2007 to 2009 greatly increased the number of young people in jobs that did not match their educational preparation.

Even when adults in their twenties with bachelor's or graduate degrees enter their chosen field, initial experiences can be discouraging. At the health department, Sharese discovered that paperwork consumed much of her day. Because each project had a deadline, the pressure of productivity weighed heavily on her. Adjusting to unanticipated disappointments in salary, supervisors, and co-workers is difficult. As new employees become aware of the gap between their expectations and reality, resignations are common. Furthermore, in careers with opportunities for

promotion, high aspirations must often be revised downward because the structure of most work settings resembles a pyramid, with fewer management and supervisory jobs. For these reasons—in addition to layoffs due to financial exigencies—workers in their twenties typically change jobs several times; three or four changes are not unusual.

Recall from our discussion of Levinson's theory that career progress often depends on the quality of a mentoring relationship. Access to an effective mentor—a person with greater experience and knowledge who is invested in the junior person's career success and who fosters a bond of trust—is jointly affected by the availability of willing people and the individual's capacity to select an appropriate individual. Most of the time, professors and senior colleagues at work fill this role. Occasionally, knowledgeable friends or relatives provide mentoring. Mentors sometimes act as teachers who enhance the person's career-related skills. At other times they serve as guides who acquaint the person with the values and customs of the work setting. When young adults have varied mentors, each providing unique forms of assistance, they benefit more in terms of career-related learning (Hall & Las Heras, 2011). Furthermore, mentoring early in a worker's career increases the likelihood of mentoring later on (Bozionelos et al., 2011). The professional and personal benefits of mentoring induce employees to provide it to others and to seek it again for themselves.

## Women and Ethnic Minorities

Women and ethnic minorities have penetrated nearly all professions, but their talents often are not developed to the fullest. Women, especially those who are members of economically disadvantaged minorities, remain concentrated in occupations that offer little opportunity for advancement, and they are underrepresented in executive and managerial roles (see Chapter 13, page 463). And although the overall difference between men's and women's earnings is smaller today than 30 years ago, it remains considerable in the majority of industrialized countries (OECD, 2015b). Currently in the United States, the average woman working full-time earns just 83 percent as much as the average man. When only workers with a bachelor's degree or higher are considered, the difference diminishes but is still substantial—88 percent (U.S. Department of Labor, 2015b).

What factors contribute to the widespread, persistent gender pay gap? In college, women more often major in education and social service fields, men in higher-paying scientific and technical fields—choices influenced by gender-stereotyped messages (see pages 464–465 in Chapter 13). And unlike the continuous career lives of most well-educated men, many women enter and exit the labor market several times, or reduce their work hours from full-time to part-time as they give birth to and rear children. Time away from a career greatly hinders advancement—a major reason that women in prestigious, male-dominated careers tend to delay or avoid childbearing.

Yet an increasing number of accomplished professional women are leaving their jobs to devote themselves full-time to child rearing—a trend that has generated mistaken, gender-

stereotyped interpretations of their “choice.” Interviews with such women reveal that the decision to leave their careers is almost always agonizing. The most common reason given is a high-pressured, inflexible work environment that offers no leeway for work–family balance (Lovejoy & Stone, 2012; Rubin & Wooten, 2007). When these women eventually return to the labor force, they often reorient, entering female-dominated occupations in the social services sector that are lower paid.

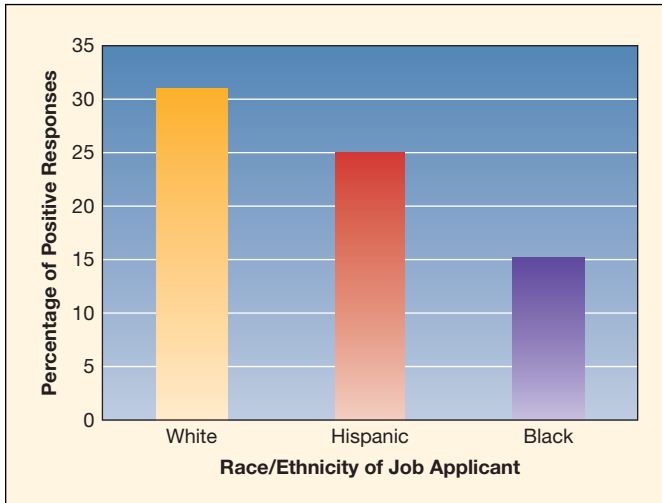

In addition, low self-efficacy with respect to male-dominated fields limits women's career progress. Women who pursue nontraditional careers usually have “masculine” traits—high achievement orientation, self-reliance, and belief that their efforts will result in success. But even those with high self-efficacy are less certain than their male counterparts that they can overcome barriers to career success. In traditionally masculine fields, newly hired women whose training is equivalent to that of newly hired men are nevertheless paid less (Lips, 2013). Also, these women may have difficulty finding supportive mentors. In one study, science professors at a broad sample of U.S. universities were sent an undergraduate student's application for a lab manager position. For half, the application bore a male name; for the other half, a female name (Moss-Racusin et al., 2012). Professors of both genders viewed the female student as less competent, less deserving of mentoring, and meriting a lower salary, though her accomplishments were identical to those of the male.

Gender-stereotyped images of women as followers rather than leaders slow advancement into top-level management positions. Mentoring by a senior-male executive predicts progress into management roles and pay gains more strongly for women in male-dominated industries than for men (Ramaswami et al., 2010). When a powerful male leader *sponsors* the advancement of a talented woman, designating her as having the qualities to succeed, senior-level decision makers are far more likely to take notice. Nevertheless, once in those positions, women are evaluated more harshly than men (Tharenou, 2013). This is especially

© RYAN MCGINNIS/ALAMY

Women in male-dominated fields, such as this scientist, usually have “masculine” traits, including high achievement orientation and self-reliance. Nevertheless, many encounter workplace barriers to career success.

**FIGURE 14.4 Relationship of job applicant race/ethnicity to employer callbacks and job offers.** The white applicant received slightly more positive responses from employers than did the Hispanic applicant, both of whom greatly exceeded the black applicant, though all three submitted the same résumé and had been matched on verbal and interpersonal skills and physical attractiveness. (From D. Pager, B. Western, & B. Bonikowski, "Discrimination in a Low-Wage Labor Market: A Field Experiment," *American Sociological Review*, 74, p. 785, copyright © 2009, American Sociological Association. Adapted by permission of SAGE Publications.)

so when women display stereotypically masculine behaviors, such as an assertive leadership style.

Despite laws guaranteeing equality of opportunity, racial and ethnic bias in career opportunities remains strong. In one study, researchers recruited two three-member teams consisting of a white, a black, and a Hispanic male job applicant, each 22 to 26 years old and matched on verbal and interpersonal skills and physical attractiveness. The applicants were assigned identical fictitious résumés (with the exception that the résumé of the white member of the second team disclosed a criminal record) and sent out to apply for 170 entry-level jobs in New York City (Pager, Western, & Bonikowski, 2009). As Figure 14.4 shows, the white applicant received callbacks or job offers from employers slightly more often than the Hispanic applicant, with the black applicant trailing far behind. When the experiment was repeated with the second team, the white felon remained slightly preferred over both minority applicants, despite their clean records.

In another similar investigation, which varied applicant qualifications within résumés, white men and women with high-quality résumés received substantially more employer callbacks than those with low-quality résumés. In contrast, having a high-quality résumé made little difference for African Americans. As the researchers noted, "Discrimination appears to bite twice, making it harder for African Americans to find a job and to improve their employability" (Bertrand & Mullainathan, 2004, p. 3). Consistent with this conclusion, African Americans spend more time searching for work, search more broadly across types of jobs to increase their chances of getting an offer, experience less stable employment, and acquire less work experience than

European Americans with equivalent qualifications (Pager & Pedulla, 2015; Pager & Shepherd, 2008).

Ethnic minority women often must surmount combined gender and racial discrimination to realize their career potential (O'Brien, Franco, & Dunn, 2014). Those who succeed frequently display an unusually high sense of self-efficacy, attacking problems head-on despite repeated obstacles to achievement. In interviews with African-American women who had become leaders in diverse fields, all reported intense persistence, fueled by supportive relationships with other women, including teachers and peers. Many described their mothers as inspiring role models who had set high standards and offered valuable advice and encouragement (Richie et al., 1997). Others mentioned support from their African-American communities and were strongly motivated to give back (Nickels & Kowalski-Braun, 2012). After having experienced positive mentoring, successful African-American women take on especially heavy mentoring obligations.

## Combining Work and Family

The majority of women with children are in the work force (see page 356 in Chapter 10), most in dual-earner marriages or cohabiting relationships. More women than men report moderate to high levels of stress in trying to meet both work and family responsibilities (Mitchell, Eby, & Lorys, 2015; Zhao, Settles, & Sheng, 2011).

When Sharese returned to her job after her children were born, she immediately felt a sense of role overload. In addition to a challenging career, she also (like most employed women) shouldered more household and child-care tasks. And both Sharese and Ernie felt torn between the desire to excel at their jobs and the desire to spend more time with each other, their children, and their friends and relatives. Persistent stress caused by role overload is linked to poorer marital relations, less effective parenting, child behavior problems, poorer job performance,

THINKSTOCK IMAGES/GETTY IMAGES

Time-flexible policies enabling employees to work from home help parents adjust work roles to meet family needs. As a result, employees feel less stressed and are more productive at work.

## Applying what we Know

### Strategies That Help Dual-Earner Couples Combine Work and Family Roles

STRATEGY	DESCRIPTION
Devise a plan for sharing household tasks.	As soon as possible in the relationship, discuss relative commitment to work and family and division of household responsibilities. Decide who does a particular chore on the basis of who has the needed skill and time, not on the basis of gender. Schedule regular times to rediscuss your plan.
Begin sharing child care right after the baby's arrival.	For fathers, strive to spend equal time with the baby early. For mothers, refrain from imposing your standards on your partner. Instead, share the role of "child-rearing expert" by discussing parenting values and concerns often. Attend a parent education course together.
Talk over conflicts about decision making and responsibilities.	Face conflict through communication. Clarify your feelings and needs and express them to your partner. Listen and try to understand your partner's point of view. Then be willing to negotiate and compromise.
Establish a balance between work and family.	Critically evaluate the time you devote to work in view of your family values and priorities. If it is too much, cut back.
Make sure your relationship receives regular loving care.	See Applying What We Know on page 482.
Press for workplace and public policies that support dual-earner-family roles.	Difficulties faced by dual-earner couples are partly due to lack of workplace and societal supports. Encourage your employer to provide benefits that help combine work and family, such as flexible work hours, parental leave with pay, and on-site high-quality, affordable child care. Communicate with lawmakers and other citizens about improving public policies for children and families.

and physical health problems (Saginak & Saginak, 2005; ten Brummelhuis et al., 2013).

Role overload is magnified for women in low-status work roles with rigid schedules and little autonomy (Repetti & Wang, 2014). Couples in prestigious careers have more control over both work and family domains. For example, Sharese and Ernie devised ways to spend more time with their children. They picked them up at child care early one day a week, compensating by doing certain work tasks on evenings and weekends. But in a Canadian study of more than 3,000 individuals in dual-earner families who were employed full-time, most coped with role overload by scaling back at home (leaving things undone) or restructuring family roles (taking over responsibilities for each other, as needed), with women doing more of this than men (Higgins, Duxbury, & Lyons, 2010). Overall, couples expected family life to accommodate to work demands. They seldom adjusted work roles to meet family needs. Although some had little flexibility at work, others simply prioritized work over family life.

Workplace supports can greatly reduce role overload, yielding substantial payoffs for employers. Among large, nationally representative samples of U.S. working adults, the more time-flexible policies available in their work settings (for example, time off to care for a sick child, choice in start and stop times, and opportunities to work from home), the less work–family conflict participants reported and the better their work performance (Banerjee & Perrucci, 2012; Halpern, 2005). Employees with several time-flexible options missed fewer days of work, less often arrived at work late or left early, felt more committed to their employer, and worked harder. They also reported fewer stress-related health symptoms.

### LOOK and LISTEN

Talk with one or more dual-earner couples about workplace supports for good parenting. Which policies are available? Which additional ones would they find especially helpful?

Effectively balancing work and family brings many benefits—a better standard of living, improved work productivity, enhanced psychological well-being, greater self-fulfillment, and happier marriages. Ernie took great pride in Sharese's dedication to both family life and career. And the skills, maturity, and self-esteem each derived from coping successfully with challenges at home strengthened their capacity to surmount difficulties at work, enhancing both career and life satisfaction (Erdogan et al., 2012; Graves, Ohlott, & Ruderman, 2007). Applying What We Know above lists strategies that help dual-earner couples attain mastery and pleasure in both spheres of life.

### Ask yourself

**CONNECT** Generate a list of capacities and skills derived from high commitment to family roles (both partner and parent) that can enhance work performance and satisfaction.

**APPLY** Write an essay aimed at convincing a company executive that family-friendly policies are "win-win" situations for both workers and employers.

**REFLECT** Ask someone who has succeeded in a career of interest to you to describe mentoring relationships that aided his or her progress.

## Summary / chapter 14

### A Gradual Transition: Emerging Adulthood (p. 470)

#### 14.1 Discuss emotional and social development during emerging adulthood, along with cultural influences and individual variations.

- In **emerging adulthood**, many young people do not view themselves as fully adult. Rather, those with economic resources engage in extended exploration of alternatives in education, work, and personal values. Identity development continues into the college years, with young people exploring in depth and revisiting commitments that fit poorly with their talents and potentials.

EDUARDO CONTRERAS/UT SAN DIEGO/ZUMAPRESS.COM

- Many emerging adults express a strong commitment to improving their communities, nation, and world, and large numbers participate in community service. Nevertheless, compared with older people, they vote in fewer numbers.
- During the late teens and twenties, religious attendance declines, continuing the trend that was under way in adolescence, though women and ethnic minority young people express greater religiosity. Regardless of religious participation, many emerging adults begin to construct an individualized faith. Those who are religious or spiritual tend to be better adjusted.
- Increased education required for entry-level jobs, gains in economic prosperity, and reduced need for young people's labor in industrialized nations have prompted the appearance of emerging adulthood. But because of its strong association with SES and higher education, some researchers do not view emerging adulthood as a distinct stage of development.

- A sizable number of emerging adults flounder, suffering from lack of direction and engaging in high levels of risky behaviors. But most young people with access to the opportunities of emerging adulthood experience it as a time of flourishing. A wide array of personal attributes and social supports, especially a warm, autonomy-supportive relationship with parents, foster resilience.

### Erikson's Theory: Intimacy versus Isolation (p. 476)

#### 14.2 According to Erikson, what personality changes take place during early adulthood?

- In Erikson's theory, young adults must resolve the conflict of **intimacy versus isolation** as they form a close relationship with a partner. The negative outcome is loneliness and self-absorption.
- Young people also focus on aspects of generativity, including parenting and contributions to society through work and community service.

### Other Theories of Adult Psychosocial Development (p. 477)

#### 14.3 Describe and evaluate Levinson's and Vaillant's psychosocial theories of adult personality development.

- Expanding Erikson's stage approach, Levinson described a series of eras in which people revise their life structure. Young adults usually construct a dream, typically involving career for men and both marriage and career for women, and form a relationship with a mentor. In their thirties, men tend to settle down, whereas many women remain unsettled.
- Also in the tradition of Erikson, Vaillant portrayed the twenties as devoted to intimacy, the thirties to career consolidation, the forties to strengthening generativity, the fifties and sixties to extending generativity in passing on cultural values, and late adulthood to reflecting on life's meaning.
- Young adults' development is far more variable today than Levinson's and Vaillant's theories depict.

#### 14.4 What is the social clock, and how does it affect development in adulthood?

- Following a **social clock**—age-graded expectations for major life events—grants confidence to young adults. Deviating from it can bring psychological distress. As age-graded expectations have become increasingly flexible, departures from social-clock life events are common and can create intergenerational tensions.

### Close Relationships (p. 478)

#### 14.5 Describe factors affecting mate selection, the components of romantic love, and the changing forms of love as relationships develop, noting cultural variations.

- Romantic partners tend to resemble each other in age, education level, ethnicity, religion, and various personal and physical attributes.
- According to an evolutionary perspective, women seek a mate with traits that help ensure children's survival, while men look for characteristics signaling sexual pleasure and ability to bear offspring. From an alternative perspective, gender roles, jointly influenced by evolutionary and cultural pressures, influence criteria for mate selection.
- According to Sternberg's **triangular theory of love**, the balance among passion, intimacy, and commitment in romantic ties changes over time. As **passionate love** gives way to **companionate love** and **compassionate love**, relationships become more intimate, committed, satisfying, and long-lasting.

PEOPLEIMAGES.COM/GETTY IMAGES

- Rather than romantic love, Eastern cultures emphasize dependency and family obligation in lifelong partnerships. Many arranged marriages succeed, with couples reporting that commitment helped strengthen their love.

#### 14.6 Describe young adults' friendships and sibling relationships and their influence on psychological well-being.

- Adult friendships, like earlier friendships, are based on trust, intimacy, and loyalty. Women's same-sex friendships tend to be more intimate than men's. After marriage, other-sex friendships decline with age for men but increase for women, who often form them in the workplace. When family experiences have been positive, adult sibling relationships often resemble friendships.

## The Family Life Cycle (p. 484)

### 14.7 Trace phases of the family life cycle that are prominent in early adulthood, and cite factors that influence these phases today.

- Wide variations exist in the sequence and timing of the **family life cycle**. Delayed home-leaving has occurred in most industrialized nations. Departures generally occur earlier for education than for full-time work or marriage; role transitions and financial circumstances often prompt a move back. Parents of young adults living at home are usually highly committed to helping their children move into adult roles.
- The average age of first marriage in the United States and Western Europe has risen. Same-sex marriages are recognized nationwide in 20 countries, including the United States.
- Both sexual majority and minority couples perceive marriage as important because it confers public legitimacy to the relationship, demonstrates commitment, and offers financial and legal benefits.
- Both **traditional marriages** and **egalitarian marriages** are affected by women's participation in the work force. Women in Western nations spend nearly twice as much time as men on housework, although men participate much more in child care than in the past. Women experiencing role overload feel particularly dissatisfied with their marriages, though equal sharing of family responsibilities enhances both partners' satisfaction.
- The transition to parenthood brings increased responsibilities, often prompting a shift to more traditional roles. After the birth of a second child, this may reverse. Gratifying marriages tend to remain so after childbirth, but troubled marriages usually become more distressed. Shared caregiving predicts greater parental happiness and positive parent–infant interaction.
- Couples with young children who engage in effective coparenting are more likely to use effective child-rearing practices, have children who are developing well, and gain in marital satisfaction.
- Parents of adolescents must establish revised relationships with their increasingly autonomous teenagers. Marital satisfaction often declines in this phase.

## The Diversity of Adult Lifestyles (p. 492)

### 14.8 Discuss the diversity of adult lifestyles, focusing on singlehood, cohabitation, and childlessness.

- Postponement of marriage has contributed to a rise in singlehood. Despite an array of drawbacks, singles typically appreciate their freedom and mobility.
- **Cohabitation** has increased, becoming the preferred mode of entry into a committed intimate partnership for young people. Compared with their Western European counterparts, Americans who cohabit before marriage tend to be less committed to their partner, and their subsequent marriages are more likely to fail. U.S. lesbian and gay cohabiting couples, however, are exceptions: Many are highly committed, with large numbers marrying after legalization of same-sex marriage in the United States.
- Voluntarily childless adults tend to be highly educated, career-oriented, and content with their lives. But involuntary childlessness interferes with adjustment and life satisfaction.

### 14.9 Cite factors that contribute to high rates of divorce and remarriage.

- Maladaptive communication patterns, younger ages at marriage, a family history of divorce, low education, economic disadvantage, and American individualism all contribute to divorce.
- Remarriages are especially vulnerable to breakup. Reasons include emphasis on practical concerns in the decision to remarry, the persistence of negative patterns of communication, the acceptance of divorce as a solution to marital difficulties, and problems adjusting to a stepfamily.

### 14.10 Discuss challenges associated with varied styles of parenthood, including stepparents, never-married parents, and gay and lesbian parents.

- Establishing stepparent–stepchild ties is difficult, especially for stepmothers and for stepfathers without children of their own. A caring relationship between remarried or cohabiting couples that includes effective coparenting, cooperation from the biological parent, and extended-family support promotes positive stepparent–stepchild ties.

© HERO IMAGES INC./ALAMY

- Never-married single parenthood is especially high among African-American young women. Unemployment among black men contributes to this trend. Even with help from extended family members, these mothers find it difficult to overcome poverty.

- Lesbian and gay parents are as effective at child rearing as heterosexual parents, and their children are as well-adjusted as those reared by heterosexual parents.

## Career Development (p. 498)

### 14.11 Discuss patterns of career development, and cite difficulties faced by women, ethnic minorities, and dual-earner couples.

- Men's career paths are usually continuous, whereas women's are often interrupted by family needs. Once young adults settle into an occupation, their progress is affected by opportunities for promotion, the broader economic environment, and access to effective mentors.
- Women and ethnic minorities have penetrated most professions, but their career advancement has been hampered by time away from the labor market, low self-efficacy with respect to male-dominated fields, lack of mentoring, and gender stereotypes. Racial and ethnic bias remains strong. Ethnic minority women who succeed display an unusually high sense of self-efficacy.
- Employed parents often experience role overload, which can be greatly reduced by workplace supports such as time-flexible policies. Effectively balancing work and family enhances standard of living, psychological well-being, marital happiness, and work performance.

## Development in Early Adulthood

PEOPLEIMAGES/GETTY IMAGES

### 18–30 YEARS

#### Physical

- Athletic skills that require speed of limb movement, explosive strength, and gross motor coordination peak early in this time period, then decline. (442)
- Athletic skills that depend on endurance, arm–hand steadiness, and aiming peak at the end of this time period, then decline. (442)
- Declines in touch sensitivity, cardiovascular and respiratory capacity, immune system functioning, and skin elasticity begin and continue throughout adulthood. (441)
- As basal metabolic rate declines, gradual weight gain begins in the middle of this decade and continues through middle adulthood. (446)
- Sexual activity increases. (452)

#### Cognitive

- If college educated, dualistic thinking declines in favor of relativistic thinking; may progress to commitment within relativistic thinking. (456–457)
- Moves from hypothetical to pragmatic thought. (458)

MYRLEEN FERGUSON CATE/PHOTODEDIT

- Narrows vocational options and settles on a specific career. (462)
- Gains in cognitive–affective complexity. (458)
- Develops expertise in a field of endeavor, which enhances problem solving. (458–459)
- May increase in creativity. (459)

BORDERLANDS/ALAMY

#### Emotional/Social

- If life circumstances permit, may engage in the extended exploration that characterizes emerging adulthood. (470–471)
- Forms a more complex self-concept that includes awareness of own changing traits and values. (470)
- If a high school graduate, is likely to enroll in higher education. (460)
- Is likely to achieve a personally meaningful identity. (470–471)
- Leaves the parental home permanently. (484–485)
- Strives to make a long-term commitment to an intimate partner. (476, 479)

ALEX FARNSWORTH/THE IMAGE WORKS

- Usually constructs a dream—an image of the self in the adult world that guides decision making. (477)
- Typically forms a relationship with a mentor. (477, 499)
- If in a high-status career, acquires professional skills, values, and credentials. (477)
- Develops mutually gratifying adult friendships and work ties. (482–483)
- May cohabit, marry, and become parents. (485–486, 489–491)
- Sibling relationships become more companionate. (484)

## 30–40 YEARS

### Physical

- Declines in vision, hearing, and the skeletal system begin and continue throughout adulthood. (441)
- In women, reproductive capacity declines, and fertility problems increase sharply after the middle of this decade. (443–444)

GEORGE DOYLE/GETTY IMAGES

- In men, semen volume and sperm motility decrease gradually in the second half of this decade; percentage of abnormal sperm rises. (444)
- Hair begins to gray and thin in the middle of this decade. (441)
- Sexual activity declines, probably as a result of the demands of daily life. (452)

### Cognitive

- Continues to develop expertise in a field of endeavor. (458–459)

ANDREW BROOKES, NATIONAL PHYSICAL LABORATORY/SCIENCE SOURCE

- Creative accomplishment often peaks in the second half of this decade, although this varies across disciplines. (459)

### Emotional/Social

- May cohabit, marry, and become parents. (485–486, 489–491)

ST. PETERSBURG TIMES/DRK SHADD/THE IMAGE

- Increasingly establishes a niche in society through family, occupational, and community commitments. (477)

### Adult Learners: Becoming a Student in Midlife

Characteristics of Returning Students •  
Supporting Returning Students

On a snowy December evening, Devin and Trisha sat down to read the holiday cards piled high on the kitchen counter. Devin's 55th birthday had just passed; Trisha would turn 48 in a few weeks. During the past year, they had celebrated their 24th wedding anniversary. These milestones, along with the annual updates they received from friends, brought the changes of midlife into bold relief.

Instead of new births or a first promotion at work, holiday cards and letters sounded new themes. Jewel's recap of the past year reflected growing awareness of a finite life-span, prompting her to reevaluate the meaningfulness of her personal life and career. She wrote:

My mood has been lighter ever since I celebrated my forty-ninth birthday. My mother passed away when she was 48, so it all feels like a gift now. I'm thinking of leaving the corporate world and starting my own business. Still dating off and on, but I haven't found anyone special.

BARRY AUSTIN PHOTOGRAPHY/GETTY IMAGES

George and Anya reported on their son's graduation from law school and their daughter Michelle's first year of university:

Anya is filling the gap created by the children's departure by returning to college for a nursing degree. After enrolling this fall, she was surprised to find herself in the same psychology class as Michelle. At first, Anya worried about handling the academic work, but after a semester of success, she's feeling more confident.

Tim's message conveyed continuing robust health, acceptance of physical changes, and a new challenge: caring for aging parents:

I used to be a good basketball player in college, but recently I noticed that my 20-year-old nephew, Brent, can dribble and shoot circles around me. It must be my age! But I ran our city marathon in September and came in seventh in the over-50 division. Brent ran, too, but he opted out a few miles short of the finish line to get some pizza while I pressed on. That must be my age, too!

The saddest news is that my dad had a bad stroke. His mind is clear, but his body is partially paralyzed. It's really upsetting because he was getting to enjoy the computer I gave him, and it was so upbeat to talk with him about it in the months before the stroke.

Middle adulthood, which begins around age 40 and ends at about 65, is marked by narrowing life options and a shrinking future as children leave home and career paths become more determined. In other ways, middle age is hard to define because wide variations in attitudes and behaviors exist. Some individuals seem physically and mentally young at age 65—active and optimistic, with fulfilling work and leisure pursuits. Others feel old at age 40—as if their lives had peaked and were on a downhill course.

Another reason middle adulthood eludes definition is that it is a contemporary period of life. Before the twentieth century, only a brief interval separated the tasks of early adulthood from those of old age. Women were often widows by their mid-fifties, before their youngest child left home. And harsh living conditions led people to accept a ravaged body as a natural part of life. As life expectancy—and, with it, health and vigor—increased over the previous century, adults became more aware of their own aging and mortality.

In this chapter, we trace physical and cognitive development in midlife. In both domains, we will encounter not just progressive declines but also sustained performance and compensating gains. As in earlier chapters, we will see that change occurs in manifold ways. Besides heredity and biological aging, our personal approach to passing years combines with family, community, and cultural contexts to affect the way we age. ●

## PHYSICAL DEVELOPMENT

Physical development in middle adulthood is a continuation of the gradual changes under way in early adulthood. Even vigorous adults notice an older body when looking in the mirror or at family photos. Hair grays and thins, new lines appear on the face, and a fuller, less youthful body shape is evident. During midlife, many individuals begin to experience life-threatening health episodes—if not in themselves, then in their partners and friends. And a shift in subjective time orientation, from “time since birth” to “time left to live” occurs, increasing consciousness of aging (Demiray & Bluck, 2014; Neugarten, 1996).

These factors lead to a revised physical self-image, with somewhat less emphasis on hoped-for gains and more on feared declines (Bybee & Wells, 2003; Frazier, Barreto, & Newman, 2012). Prominent concerns of 40- to 65-year-olds include getting a fatal disease, being too ill to maintain independence, and losing mental capacities. Unfortunately, many middle-aged adults fail to embrace realistic alternatives—becoming more physically fit and developing into healthy, energetic older adults. Although certain aspects of aging cannot be controlled, people can do much to promote physical vigor and good health in midlife.

## Physical Changes

**15.1** Describe the physical changes of middle adulthood, paying special attention to vision, hearing, the skin, muscle–fat makeup, and the skeleton.

**15.2** Describe reproductive changes in both sexes, along with associated physical and emotional symptoms, during middle adulthood.

As she dressed for work one morning, Trisha remarked jokingly to Devin, “I think I’ll leave the dust on the mirror so I can’t see the wrinkles and gray hairs.” Catching sight of her image, she continued in a more serious tone. “And look at this fat—it just doesn’t want to go! I need to fit some regular exercise into my life.” In response, Devin glanced soberly at his own enlarged midriff.

At breakfast, Devin took his glasses on and off and squinted while reading the paper. “Trish—what’s the eye doctor’s phone number? I’ve got to get these bifocals adjusted again.” As they conversed between the kitchen and the adjoining den, Devin sometimes asked Trisha to repeat herself. And he kept turning up the radio and TV volume. “Does it need to be that loud?” Trisha would ask. Devin’s hearing seemed less keen than before.

In the following sections, we look closely at the major physical changes of midlife. As we do so, you may find it helpful to refer back to Table 13.1 on page 441, which provides a summary.

### Vision

During the forties, difficulty reading small print is common, due to thickening of the lens combined with weakening of the muscle that enables the eye to *accommodate* (adjust its focus) to nearby objects. As new fibers appear on the surface of the lens, they compress older fibers toward the center, creating a thicker, denser, less pliable structure. By age 50, the accommodative ability of the lens is one-sixth of what it was at age 20. Around age 60, the lens loses its capacity to adjust to objects at varying distances entirely, a condition called **presbyopia** (literally, “old eyes”). As the lens loses elasticity, the eye rapidly becomes more farsighted between ages 40 and 60 (Charman, 2008). Corrective lenses—or, for nearsighted people, bifocals—ease reading problems.

A second set of changes limits ability to see in dim light, which declines at twice the rate of daylight vision. Throughout adulthood, the size of the pupil shrinks and the lens yellows. In addition, starting at age 40, the *vitreous* (transparent gelatin-like substance that fills the eye) develops opaque areas, reducing the amount of light reaching the retina. Changes in the lens and vitreous also cause light to scatter within the eye, increasing sensitivity to glare. Devin had always enjoyed driving at night, but now he sometimes had trouble making out signs and moving objects (Owsley, 2011; Sørensen, White, & Ramchandran, 2016). And his vision was more disrupted by bright light sources, such as headlights of oncoming cars. Yellowing of the lens and

increasing density of the vitreous also limit color discrimination, especially at the green–blue–violet end of the spectrum (Paramei, 2012). Occasionally, Devin had to ask whether his sport coat, tie, and socks matched.

Besides structural changes in the eye, neural changes in the visual system occur. Gradual loss of rods and cones (light- and color-receptor cells) in the retina and of neurons in the optic nerve (the pathway between the retina and the cerebral cortex) contributes to visual declines. By midlife, half the *rods* (which enable vision in dim light) are lost (Grossniklaus et al., 2013; Owsley, 2011). And because rods secrete substances necessary for survival of *cones* (which enable daylight and color vision), gradual loss of cones follows. In addition, decreased blood supply to the retina, due to degeneration of retinal blood vessels, causes it to thin and become less sensitive.

Middle-aged adults are at increased risk of **glaucoma**, a disease in which poor fluid drainage leads to a buildup of pressure within the eye, damaging the optic nerve. Glaucoma affects nearly 2 percent of people over age 40, more often women than men. It typically progresses without noticeable symptoms and is a leading cause of blindness. Heredity contributes to glaucoma, which runs in families: Siblings of people with the disease have a tenfold increased risk, and it occurs three to four times as often in African Americans and Hispanics as in European Americans (Guedes, Tsai, & Loewen, 2011). Starting in midlife, eye exams should include a glaucoma test. Drugs that promote release of fluid and surgery to open blocked drainage channels prevent vision loss.

## Hearing

An estimated 14 percent of Americans between ages 45 and 64 suffer from hearing loss, often resulting from adult-onset hearing impairments (Center for Hearing and Communication, 2016). Although some conditions run in families and may be hereditary, most are age-related, a condition called **presbycusis** (“old hearing”).

As we age, inner-ear structures that transform mechanical sound waves into neural impulses deteriorate through natural cell death or reduced blood supply caused by atherosclerosis. Processing of neural messages in the auditory cortex also weakens. The first sign of hearing loss, around age 50, is a noticeable decline in sensitivity to high-frequency sounds, which gradually extends to all frequencies. The ability to distinguish sounds occurring in close succession also recedes. Gradually, human speech becomes more difficult to make out, especially rapid speech and speech against a background of voices (Ozmerai et al., 2016; Wettstein & Wahl, 2016). Still, throughout middle adulthood, most people hear reasonably well across a wide frequency range. And African tribal peoples display little age-related hearing loss (Jarvis & van Heerden, 1967; Rosen, Bergman, & Plester, 1962). These findings suggest factors other than biological aging are involved.

Men’s hearing tends to decline earlier and more rapidly than women’s, a difference associated with cigarette smoking, intense

THOMAS BARWICK/STONE/GETTY IMAGES

A worker uses a grinder to smooth a metal surface in a steel manufacturing facility. Men’s hearing declines more rapidly than women’s, a difference associated with several factors, including intense noise in some male-dominated occupations.

noise and chemical pollutants in some male-dominated occupations, and (at older ages) high blood pressure and cerebrovascular disease, or strokes that damage brain tissue (Van Eyken, Van Camp, & Van Laer, 2007; Wettstein & Wahl, 2016). Government regulations requiring industries to implement such safeguards as noise monitoring, provision of earplugs, pollution control, and regular hearing tests have greatly reduced hearing damage (U.S. Department of Labor, 2016b). But some employers do not comply fully.

Most mid- and late-life adults with hearing difficulties benefit from hearing aids, though only a minority wear them. Many regard a hearing aid as embarrassing, are unwilling to take time to adjust to using it, judge that it is not effective enough, or find it too costly (Li-Korotky, 2012). When perception of the human voice is affected, speaking to the person patiently, clearly, and with good eye contact, in an environment with reduced background noise, aids understanding.

## Skin

Our skin consists of three layers: (1) the *epidermis*, or outer protective layer, where new skin cells are constantly produced; (2) the *dermis*, or middle supportive layer, consisting of connective tissue that stretches and bounces back, giving the skin elasticity; and (3) the *hypodermis*, an inner fatty layer that adds to the soft lines and shape of the skin. As we age, the epidermis becomes less firmly attached to the dermis, fibers in the dermis thin and lose their elasticity, cells in both the epidermis and dermis decline in water content, and fat in the hypodermis diminishes, leading the skin to wrinkle, loosen, and feel dry.

In the thirties, lines develop on the forehead as a result of smiling, frowning the brow, and other facial expressions. In the forties, these become more pronounced, and “crow’s-feet” appear around the eyes. Gradually, the skin loses elasticity and begins to

sag, especially on the face, arms, and legs (Khavkin & Ellis, 2011). After age 50, “age spots,” collections of pigment under the skin, increase. Blood vessels in the skin become more visible as the fatty layer thins.

Because sun exposure hastens wrinkling, loosening, and spotting, individuals who have spent much time outdoors without proper skin protection look older than their contemporaries. And partly because the dermis of women is not as thick as that of men and estrogen loss accelerates thinning and decline in elasticity, women’s skin ages more quickly (Thornton, 2013).

## Muscle–Fat Makeup

As Trisha and Devin make clear, weight gain—“middle-age spread”—is a concern for both men and women. A common pattern of change is an increase in body fat and a loss of lean body mass (muscle and bone). The rise in fat largely affects the torso and occurs as fatty deposits within the body cavity; as noted earlier, fat beneath the skin on the limbs declines. On average, size of the abdomen increases 7 to 14 percent. Although a large portion is due to weight gain, age-related changes in muscle–fat makeup also contribute (Stevens, Katz, & Huxley, 2010). In addition, sex differences in fat distribution appear. Men accumulate more on the back and upper abdomen, women around the waist and upper arms (Sowers et al., 2007). Muscle mass declines very gradually in the forties and fifties, largely due to atrophy of fast-twitch fibers, responsible for speed and explosive strength.

Yet, as indicated in Chapter 13, large weight gain and loss of muscle power are not inevitable. With age, people must gradually reduce caloric intake to adjust for the age-related decline in basal metabolic rate (see page 446). In nonhuman animals, dietary restraint dramatically increases longevity while sustaining health and vitality. Currently, researchers are identifying the biological mechanisms involved and studying their relevance to humans (see the Biology and Environment box on the following page).

Women, who tend to be less active than men, experience a more rapid age-related decline in muscle mass and function (Charlier et al., 2015). But weight-bearing exercise that includes resistance training (placing a moderately stressful load on the muscles) can offset both excess weight and muscle loss. Consider Devin’s 57-year-old friend Tim, who for years has ridden his bike to and from work on weekdays, jogged on weekends, and engaged in a twice-a-week weight-lifting regimen—averaging an hour of vigorous activity each day. Like many endurance athletes, he maintained the same weight and muscular physique throughout early and middle adulthood.

## Skeleton

As new cells accumulate on their outer layers, the bones broaden with age, but their mineral content declines, so they become more porous. This leads to a gradual loss in bone density that begins around age 40 and accelerates in the fifties, especially among women (Clarke & Khosla, 2010). Women’s reserve of bone minerals is lower than men’s to begin with. And following menopause, the favorable impact of estrogen on bone mineral

absorption is lost. Among men, testosterone is similarly protective, and as they age, testosterone and bone density decline (Gold, 2016). Reduction in bone density during middle and late adulthood is substantial—about 8 to 12 percent in men and 20 to 30 percent in women.

Loss of bone strength causes the disks in the spinal column to collapse. Consequently, height may drop by as much as 1 inch by age 60, a change that will hasten thereafter. In addition, the weakened bones cannot support as much load: They fracture more easily and heal more slowly. A healthy lifestyle—including weight-bearing exercise, adequate calcium and vitamin D intake, and avoidance of smoking and heavy alcohol consumption—can slow bone loss in postmenopausal women by as much as 30 to 50 percent (Rizzoli, Abraham, & Brandi, 2014).

When bone loss is very great, it leads to a debilitating disorder called *osteoporosis*. We will take up this condition shortly when we consider illness and disability.

## Reproductive System

The midlife transition in which fertility declines is called the **climacteric**. In women, it brings an end to reproductive capacity; in men, by contrast, fertility diminishes but is retained.

**Reproductive Changes in Women.** The changes involved in women’s climacteric occur gradually over a 10-year period, during which the production of estrogen drops. As a result, the number of days in a woman’s monthly cycle shortens from about 28 in her twenties and thirties to perhaps 23 by her late forties, and her cycles become more irregular. In some, ova are not released; when they are, more are defective (see Chapter 2, page 50). The climacteric concludes with **menopause**, the end of menstruation and reproductive capacity. This occurs, on average, in the early fifties among North American, European, and East Asian women, although the age range extends from the late thirties to the late fifties (Rossi, 2004a; Siegel, 2012). Women who smoke or who have not borne children tend to reach menopause earlier.

STEVE PREZANT/GETTY IMAGES/IMAGE SOURCE

African-American women, who generally view menopause as normal, inevitable, and even welcome, experience less irritability and moodiness during this transition than European-American women.

## Biology and Environment

### Anti-Aging Effects of Dietary Calorie Restriction

Scientists have long known that dietary calorie restriction in nonprimate animals slows aging while maintaining good health and body functions. Rats and mice fed 30 to 50 percent fewer calories than they would freely eat beginning in early life show various physiological health benefits, lower incidence of chronic diseases, and up to 50 percent increase in length of life (Fontana & Hu, 2014). Mild to moderate calorie restriction begun after rodents reach physical maturity also slows aging and extends longevity, though to a lesser extent. Other studies reveal similar dietary-restriction effects in mice, fleas, spiders, worms, fish, and yeast.

#### Nonhuman Primate Research

Would primates, especially humans, also benefit from a restricted diet? Researchers have been tracking health indicators in rhesus monkeys after placing some on regimens of 30 percent reduced calories starting at a young age and sustained into adulthood. More than two decades of longitudinal findings revealed that, compared with freely eating controls, dietary-restricted monkeys were smaller but not overly thin. They accumulated body fat differently—less on the torso, a type of fat distribution that reduces middle-aged humans' risk of heart disease.

Calorie-restricted monkeys also had a lower body temperature and basal metabolic rate—changes that suggest they shifted physiological processes away from growth to maintenance and repair functions. Consequently, like calorie-restricted rodents, they seemed better able to withstand severe physical stress, such as surgery and infectious disease (Rizza, Veronese, & Fontana, 2014).

Among physiological processes mediating these benefits, three seem most powerful. First, calorie restriction inhibited production of free radicals, which at high levels cause cellular deterioration (see page 440 in Chapter 13) (Carter et al., 2007). Second, calorie restriction protected against chronic inflammation of body tissues, which results in tissue damage

and is involved in many diseases of aging (Chung et al., 2013). Third, calorie restriction reduced blood glucose and improved insulin sensitivity, thereby lessening the risk of diabetes and cardiovascular disease (Fontana, 2008). Lower blood pressure and cholesterol and a high ratio of “good” to “bad” cholesterol in calorie-restricted primates strengthened these effects.

Tracking of the monkeys' ages at death revealed inconsistent findings on whether calorie-restriction extended length of life. But limiting food intake dramatically reduced the incidence of age-related diseases, including arthritis, cancer, cardiovascular disease, and diabetes, as well as decline in brain volume, sensory functioning, and muscle mass (Colman et al., 2009; Mattison et al., 2012). In sum, the calorie-restricted monkeys clearly benefited from more years of healthy life.

#### Human Research

Prior to World War II, residents of the island of Okinawa consumed an average of 20 percent fewer calories (while maintaining a healthy diet) than mainland Japanese citizens. Their restricted diet was associated with a 60 to 70 percent reduction in incidence of deaths due to cancer and cardiovascular disease. Recent generations of Okinawans no longer show these health and longevity advantages (Gavrilova & Gavrilov, 2012). The reason, some researchers speculate, is the introduction of Westernized food, including fast food, to Okinawa.

Similarly, normal-weight and overweight people who engaged in self-imposed calorie restriction for 1 to 12 years display health benefits. These include reduced blood glucose, cholesterol, blood pressure, and plaque accumulation on the walls of the arteries, and a stronger immune-system response than individuals eating a typical Western diet (Fontana, Klein, & Holloszy, 2010). And experimental

An Okinawan grandfather and grandson enjoy an afternoon of kite flying. Before World War II, residents of Okinawa consumed a restricted diet that was associated with health benefits and longer life. Recent generations no longer show these advantages, possibly due to the introduction of Westernized food to Okinawa.

evidence involving random assignment to calorie-restricted and nonrestricted conditions reveals that restricted participants again display improved cardiovascular and other health indicators, suggesting reduced risk of age-related disease (Redman & Ravussin, 2011; Rizza, Veronese, & Fontana, 2014).

Though life-extending effects remain uncertain in primates (including humans), the diverse health benefits of limiting calorie intake are now well-established. They seem to result from a physiological response to food scarcity that evolved to enhance the body's capacity to survive adversity. Nevertheless, few people would be willing to maintain a substantially reduced diet for most of their lifespan. As a result, scientists have begun to explore *calorie-restriction mimetics*—natural and synthetic drug compounds that might yield the same health effects as calorie restriction, without dieting (Ingram & Roth, 2015). These investigations are still in their early stages.

Following menopause, estrogen declines further, causing the reproductive organs to shrink in size, the genitals to be less easily stimulated, and the vagina to lubricate more slowly during arousal. As a result, complaints about sexual functioning increase, with about 35 to 40 percent of women reporting difficulties, especially among those with health problems or whose partners have sexual performance problems (Thornton, Chervenak, & Neal-Perry, 2015). The drop in estrogen also means that it no longer helps protect against aging of the skin, loss of bone mass, and accumulation of plaque on the walls of the arteries by boosting “good cholesterol” (high-density lipoprotein).

The period leading up to and following menopause is often accompanied by emotional and physical symptoms, including mood fluctuations and *hot flashes*—sensations of warmth accompanied by a rise in body temperature and redness in the face, neck, and chest, followed by sweating. Hot flashes—which may occur during the day and also, as *night sweats*, during sleep—affect more than 50 percent of women in Western industrialized nations (Takahashi & Johnson, 2015). Typically, they are not severe: Only about 1 in 12 women experiences them every day. On average, hot flashes persist for four years, but in some women, they continue for a decade. Although women approaching menopause tend to report increased irritability and less satisfying sleep, research using EEG and other neurobiological measures finds no links between menopause and changes in quantity or quality of sleep (Baker et al., 2015; Lamberg, 2007). Frequent hot flashes, however, are associated with repeated night wakings and poor sleep.

Furthermore, longitudinal evidence reveals that depressive episodes rise during the climacteric, though women who have a history of depression, who are experiencing highly stressful life events, or who harbor negative attitudes toward menopause and aging are at greatest risk (Bromberger et al., 2011; Freeman et al., 2006; Vivian-Taylor & Hickey, 2014). The hormonal changes of the climacteric seem to elevate depressive symptoms, especially in vulnerable women. With the final menstrual period, as hormone levels stabilize, the incidence of depression diminishes (Freeman et al., 2014; Gibson et al., 2012). But as Figure 15.1 reveals, women with a previous history of depression are far more likely than those with no history to continue feeling depressed after menopause. Their difficulties merit serious evaluation and treatment.

Compared with North American, European, African, and Middle Eastern women, Asian women report fewer menopausal complaints, including hot flashes (Obermeyer, 2000; Richard-Davis & Wellons, 2013). Asian diets, which are high in soy-based foods—a rich source of plant estrogen—may be involved.

**Hormone Therapy.** To reduce the physical discomforts of menopause, doctors may prescribe **hormone therapy**, or low daily doses of estrogen. Hormone therapy comes in two types: (1) estrogen alone, or *estrogen replacement therapy (ERT)*, for women who have had hysterectomies (surgical removal of the uterus); and (2) estrogen plus progesterone, or *hormone replace-*

**FIGURE 15.1** Percentage of women with severe depressive symptoms in the years leading up to and following menopause. A longitudinal investigation of 200 randomly selected women residing in Philadelphia revealed an elevated incidence of severe depression during the years preceding menopause (climacteric) that diminished after menopause. Women with a previous history of depression were at far greater risk: Following menopause, most who had been severely depressed during the climacteric continued to feel depressed. In contrast, depressive symptoms nearly evaporated in women with no history of depression. (Based on Freeman et al., 2014.)

*ment therapy (HRT)*, for other women. Combining estrogen with progesterone lessens the risk of cancer of the endometrium (lining of the uterus), which has long been known as a serious side effect of hormone therapy.

Hormone therapy is highly successful at counteracting hot flashes and vaginal dryness. It also offers some protection against bone deterioration. Nevertheless, more than 20 experiments, in which nearly 43,000 women had been randomly assigned to take hormone therapy (ERT or HRT) or a sugar pill for at least one year and were followed for an average of seven years, revealed an array of negative consequences. Hormone therapy was associated with an increase in heart attack, stroke, blood clots, breast cancer, gallbladder disease, and deaths from lung cancer. ERT, when compared with HRT, intensified the risk of blood clots, stroke, and gallbladder disease. And women age 65 and older taking HRT showed an elevated risk of Alzheimer’s disease and other dementias (Marjoribanks et al., 2012).

On the basis of available evidence, women and their doctors should make decisions about hormone therapy carefully. For those who opt to use it, taking the lowest dose possible for the shortest time possible in the early menopausal years minimizes risk (Mirkin et al., 2014). Women with family histories of cardiovascular disease or breast cancer are advised against hormone therapy. Fortunately, the number of alternative treatments is increasing. New estrogen-based drugs with fewer side effects reduce hot flashes and vaginal dryness and protect the bones (Mintziori, 2015). A relatively safe migraine-headache medica-

tion, gabapentin, substantially lessens hot flashes, perhaps by acting on the brain's temperature regulation center. At high doses, which still appear safe, gabapentin is nearly as effective as hormone therapy. Several antidepressant drugs are helpful as well (Roberts & Hickey, 2016).

**Women's Attitudes Toward Menopause.** Wide variations exist in the meanings women assign to menopause, depending on how they interpret the event in relation to their past and future lives. Jewel, who had wanted marriage and family but not attained these goals, viewed menopause as traumatic. Her sense of physical competence was still bound up with the ability to have children. Physical symptoms, or the expectation of those symptoms, can also trigger negative attitudes, such as stereotyped views of menopausal women as “irritable,” “depressed,” “old,” or having “lost femininity” (Elavsky & McAuley, 2007; Marván, Castillo-López, & Arroyo, 2013; Sievert & Espinosa-Hernandez, 2003).

Many women, however, find menopause to be little or no trouble, regard it as a new beginning, and report improved quality of life (Mishra & Kuh, 2006). When more than 2,000 U.S. women were asked what their feelings were about no longer menstruating, nearly 50 percent of those experiencing changes in their menstrual cycles, and 60 percent of those whose periods had ceased, said they felt relieved (Rossi, 2004a). Most do not want more children and are thankful to be freed from worry about birth control. And highly educated women usually have more positive attitudes toward menopause than those with less education (Pitkin, 2010).

Compared with previous generations, the baby-boom generation seems more accepting of menopause (Avis & Crawford, 2006). Their strong desire to cast aside previous gender-stereotyped views (such as menopause as a sign of decay and disease), their more active approach to seeking health information, and their greater willingness to openly discuss sexual topics may contribute to their generally positive adaptation.

Other research suggests that African-American women hold favorable views. In several studies, they reported less irritability and moodiness than European Americans. They rarely spoke of menopause in terms of physical aging but, instead, regarded it as normal, inevitable, and even welcome (Melby, Lock, & Kaufert, 2005; Sampselle et al., 2002). Several African Americans expressed exasperation at society's readiness to label as “crazy” middle-aged women's authentic reactions to work- or family-based stressors that often coincide with menopause. And in an investigation of more than 13,000 U.S. women, ages 40 to 55 and diverse in ethnicity, other factors—SES, physical health, lifestyle factors (smoking, diet, exercise, weight gain), and especially psychological stress—overshadowed menopausal status and three common symptoms (hot flashes, night sweats, and vaginal dryness) in impact on self-rated quality of life (Avis et al., 2004).

The wide variation in physical symptoms and attitudes indicates that menopause is not just a hormonal event; it is also affected by cultural beliefs and practices. The Cultural Influences

box on page 514 provides a cross-cultural look at women's experience of menopause.

**Reproductive Changes in Men.** Although men also experience a climacteric, no male counterpart to menopause exists. Both quantity and motility of sperm decrease from the twenties on, and quantity of semen diminishes after age 40, negatively affecting fertility in middle age (Gunes et al., 2016). Still, sperm production continues throughout life, and men in their nineties have fathered children. Testosterone production also declines with age, though less so in healthy men who continue to engage in sexual activity, which stimulates cells that release testosterone.

Reduced testosterone plays a major role in diminishing blood flow to and changes in connective tissue in the penis. As a result, more stimulation is required for an erection, and it may be harder to maintain. The inability to attain an erection when desired can occur at any age, but it becomes more common in midlife: By age 60, 20 to 40 percent of men report difficulties, with frequency and severity rising with age (Shamloul & Ghanem, 2013).

An episode or two of impotence is not serious, but repeated bouts can lead some men to fear that their sex life is over and undermine their self-image. Viagra, Cialis, and other drugs that increase blood flow to the penis offer temporary relief from erectile dysfunction. Publicity surrounding these drugs has prompted more open discussion of erectile dysfunction and encouraged more men to seek treatment. But those taking the medications are often not adequately screened for the host of factors besides declining testosterone that contribute to impotence, including disorders of the nervous, cardiovascular, and endocrine systems; anxiety and depression; pelvic injury; and loss of interest in one's sexual partner (Mola, 2015). Although drugs for impotence are generally safe, a few users have experienced serious vision or hearing loss (Lambda & Anderson-Nelson, 2014; Shamloul & Ghanem, 2013). In men with high blood pressure or atherosclerosis, the medications heighten the risk of constricting blood vessels in the retina and optic and auditory nerves, causing permanent damage.

## Ask yourself

**CONNECT** Compare ethnic variations in attitudes toward menopause with ethnic variations in reactions to menarche and early pubertal timing (pages 374–375 and page 377 in Chapter 11). Did you find similarities? Explain.

**APPLY** Between ages 40 and 50, Nancy gained 20 pounds. She also began to have trouble opening tightly closed jars, and her calf muscles ached after climbing a flight of stairs. “Exchanging muscle for fat must be an inevitable part of aging,” Nancy thought. Is she correct? Why or why not?

**REFLECT** What factors would you consider, or advise others to consider, before using hormone therapy to reduce menopausal symptoms?

## Cultural Influences

### Menopause as a Biocultural Event

**B**iology and culture join forces to influence women's response to menopause, making it a *biocultural event*. In Western industrialized nations, menopause is “medicalized”—regarded as a syndrome of physical and emotional symptoms requiring treatment.

Yet change the circumstances in which menopause is evaluated, and attitudes change as well. In one study, nearly 600 men and women between ages 19 and 85 described their view of menopause in one of three contexts—as a medical problem, as a life transition, or as a symbol of aging (Gannon & Ekstrom, 1993). The medical context evoked many more negative statements than the other contexts.

Research in non-Western cultures reveals that middle-aged women's social status also affects the experience of menopause. In societies where older women are respected and mother-in-law and grandmother roles bring new privileges and responsibilities, complaints about menopausal symptoms are rare (Fuh et al., 2005). Perhaps in part for this reason, women in Asian nations report fewer discomforts. And their symptoms usually differ from those of Western women.

Though they rarely complain of hot flashes, the most frequent symptoms of Asian women are back, shoulder, and joint pain—a possible biological variation from other ethnic groups (Haines et al., 2005; Huang, 2010). In midlife, women in Asian cultures attain peak respect and responsibility. Typically their days are filled with monitoring the household economy, attending to grandchildren, caring for depen-

dent parents-in-law, and employment. Asian women seem to interpret menopausal distress in light of these socially valued commitments. In Japan, neither women nor their doctors consider menopause to be a significant marker of female middle age. Rather, midlife is viewed as an extended period of “socially recognized, productive maturity” (Menon, 2001, p. 58).

A comparison of rural Mayan women of the Yucatán with rural Greek women on the island of Evia reveals additional biocultural influences on the menopausal experience (Beyene, 1992; Beyene & Martin, 2001; Mahady et al., 2008). In both societies, aging is associated with increased status, and menopause brings release from child rearing and more time for leisure activities. Otherwise, the Mayan and Greek women differ greatly.

Yucatán Mayan women marry as teenagers. By 35 to 40, they have given birth to many children but rarely menstruated because of repeated pregnancies and breastfeeding. They also experience menopause up to 10 years earlier than their counterparts in developed nations, perhaps because of additional physical stressors, such as poor nutrition and heavy physical work. Eager for childbearing to end, they look forward to menopause, describing it with such phrases as “being happy” and “free like a young girl again.” None report hot flashes or any other symptoms.

Like North Americans, rural Greek women use birth control to limit family size, and most report hot flashes and sweating at menopause. But they regard these as temporary discom-

© CHRIS HAIGH/ALAMY

For these rural Mayan women of the Yucatán, menopause brings freedom. After decades of childbearing, Mayan women look forward to menopause, describing it as “being happy” and “free like a young girl again.”

forts that will stop on their own, not as medical symptoms requiring treatment. When asked what they do about hot flashes, the Greek women reply, “Pay no attention,” “Go outside for fresh air,” and “Throw off the covers at night.”

Does frequency of childbearing affect menopausal symptoms, as this contrast between Mayan and Greek women suggests? More research is needed to be sure. At the same time, the difference between North American and Greek women in attitudes toward and management of hot flashes is striking. This—along with other cross-cultural findings—highlights the combined impact of biology and culture on menopausal experiences.

## Health and Fitness

**15.3** Discuss sexuality in middle adulthood and its association with relationship satisfaction.

**15.4** Discuss cancer, cardiovascular disease, and osteoporosis, noting risk factors and interventions.

**15.5** Discuss the association of hostility and anger with heart disease and other health problems.

In midlife, about 85 percent of Americans rate their health as either “excellent” or “good”—still a large majority, but lower

than the 95 percent figure in early adulthood (Zajacova & Woo, 2016). Whereas younger people usually attribute health complaints to temporary infections, middle-aged adults more often point to chronic diseases. As we will see, among those who rate their health unfavorably, men are more likely to suffer from fatal illnesses, women from nonfatal, limiting health problems.

In addition to typical negative indicators—major diseases and disabling conditions—our discussion takes up sexuality as a positive indicator of health. Before we begin, it is important to note that our understanding of health in middle and late adulthood is limited by insufficient research on women and ethnic

minorities. Most studies of illness risk factors, prevention, and treatment have been carried out on men. Fortunately, this situation is changing. For example, the Women’s Health Initiative (WHI)—a commitment by the U.S. federal government, extending from 1993 to 2005, to study the impact of various lifestyle and medical prevention strategies on the health of nearly 162,000 postmenopausal women of all ethnic groups and SES levels—has led to important findings, including health risks associated with hormone therapy, discussed earlier. Two five-year extensions, involving annual health updates from 115,000 WHI participants in 2005–2010, and 94,000 participants in 2010–2015, continue to yield vital information.

## Sexuality

The overwhelming majority of research on sexuality in midlife focuses on heterosexual married couples and, to a lesser extent, cohabiting couples. Little is known about the sexual activity of the growing numbers of middle-aged adults who are single and dating. Research on middle-aged dating, cohabiting, and married same-sex couples is also sparse.

*Frequency* of sexual activity among heterosexual couples tends to decline in midlife, but for most, the drop is modest. Surveys of large, nationally representative samples of U.S. adults reveal that even in the latter years of middle adulthood (ages 55 to 64), the overwhelming majority of married and cohabiting adults are sexually active (about 90 percent of men and 80 percent of women) (Thomas, Hess, & Thurston, 2015; Waite et al., 2009). And as Figure 15.2 reveals, most sexually active midlifers report having sex regularly—more than once a month or once a week.

Longitudinal research reveals that stability of sexual activity is far more typical than dramatic change. Couples who have sex often in early adulthood continue to do so in midlife (Dennerstein & Leher, 2004). And the best predictor of sexual frequency is relationship satisfaction, an association that is probably bidirectional (Karraker & DeLamater, 2013; Thomas, Hess, & Thurston, 2015). Sex is more likely in the context of a happy intimate bond, and couples who have sex often probably view their relationship more positively.

Nevertheless, *intensity* of sexual response diminishes in midlife due to physical changes of the climacteric. Both men and women take longer to feel aroused and to reach orgasm. If partners perceive each other as less attractive, this may contribute to a drop in sexual desire. Yet in the context of a positive outlook, sexual activity can become more satisfying. Devin and Trisha, for example, viewed each other’s aging bodies with acceptance and affection—as a sign of their enduring and deepening relationship. And with greater freedom from the demands of work and family, their sex life became more spontaneous. The majority of married people over age 50 say that sex is an important component of a healthy couple relationship (Das, Waite, & Laumann, 2012). And most find ways to overcome difficulties with sexual functioning. One happily married 52-year-old woman commented, “We know what we are doing, we’ve had plenty of practice (laughs), and I would never have believed

**FIGURE 15.2** Frequency of sexual activity among sexually active middle-aged women. In a survey of a nationally representative sample of over 1,000 U.S. women, those who were sexually active declined in frequency with which they engaged in sex over middle adulthood. Still, among 55- to 64-year-olds, more than one-third reported having sex at least once a week, and a similar percentage at least once a month. (Based on Thomas, Hess, & Thurston, 2015.)

that it gets better as you get older, but it does” (Gott & Hincliff, 2003, p. 1625).

When surveys include married, cohabiting, and single people, a striking gender difference in age-related sexual activity appears. The proportion of U.S. men with no sexual partners in the previous year increases only slightly from the thirties to the late fifties, from 8 to 12 percent. In contrast, the rise for women is dramatic, from 9 to about 35 to 40 percent, a gender gap that becomes even larger in late adulthood (Lindau et al., 2007; Thomas, Hess, & Thurston, 2015; Waite et al., 2009). A higher male mortality rate and the value women place on affection and continuity in sexual relations make partners less available to them. Taken as a whole, the evidence reveals that sexual activity in midlife, as in earlier periods, is the combined result of biological, psychological, and social forces.

## Illness and Disability

As Figure 15.3 on page 516 shows, cancer and cardiovascular disease are the leading causes of U.S. deaths in middle age. Unintentional injuries, though still a major health threat, occur at a lower rate than in early adulthood, largely because motor vehicle collisions decline. Despite a rise in vision problems, middle-aged adults’ many years of driving experience and greater cautiousness may reduce these deaths. In contrast, falls resulting in bone fractures and death more than double from early to middle adulthood (Centers for Disease Control and Prevention, 2014e).

As in earlier decades, economic disadvantage is a strong predictor of poor health and premature death, with SES differences widening in midlife (Agigoroaci, 2016). And largely because of

**FIGURE 15.3** Leading causes of death among people age 45 to 64 in the United States. Men are more vulnerable than women to each leading cause of death. Cancer is the leading killer of both sexes, by a far smaller margin over cardiovascular disease for men than for women. (Based on Heron, 2015.)

more severe poverty and lack of universal health insurance, the United States continues to exceed most other industrialized nations in death rates from major causes (OECD, 2015d). Furthermore, men are more vulnerable than women to most health problems. Among middle-aged men, cancer deaths exceed cardiovascular disease deaths by a small margin; among women, cancer is by far the leading cause of death (refer again to Figure 15.3). Finally, as we take a closer look at illness and disability in the following sections, we will encounter yet another familiar theme: the close connection between psychological and physical well-being. Personality traits that magnify stress—especially hostility and anger—are serious threats to health in midlife.

**Cancer.** From early to middle adulthood, the death rate due to cancer multiplies tenfold, accounting for about 30 percent of all midlife deaths in the United States (Heron, 2015). Although the incidence of many types of cancer is currently leveling off or

declining, cancer mortality was on the rise for many decades, largely because of a dramatic increase in lung cancer due to cigarette smoking. Lung cancer is the most common cause of cancer deaths in both genders, worldwide. Over the past 25 years, its incidence dropped in men; 60 percent fewer smoke today than in the 1950s. In contrast, lung cancer has only recently begun to decrease in women after a long period of increase, due to large numbers of women taking up smoking in the decades after World War II (American Cancer Society, 2015c).

Cancer occurs when a cell's genetic program is disrupted, leading to uncontrolled growth and spread of abnormal cells that crowd out normal tissues and organs. Why does this happen? Mutations of three main kinds contribute to cancer. Some result in *oncogenes* (cancer genes) that directly undergo abnormal cell duplication. Others interfere with the activity of *tumor suppressor genes* so they fail to keep oncogenes from multiplying. And a third type of mutation disrupts the activity of *stability genes*, which normally keep genetic alterations to a minimum by repairing subtle DNA mistakes that occur either during normal cell duplication or as a result of environmental agents (Ewald & Ewald, 2012). When stability genes do not function, mutations in many other genes occur at a higher rate.

Each of these cancer-linked mutations can be either *germ-line* (due to an inherited predisposition) or *somatic* (occurring in a single cell, which then multiplies) (see page 49 in Chapter 2 to review). Recall from Chapter 13 that according to one theory, error in DNA duplication increases with age, with cell repair becoming less efficient. Environmental toxins may initiate or intensify this process.

Figure 15.4 shows the incidence of the most common types of cancer. For cancers that affect both sexes, men are generally more vulnerable than women. The difference may be due to genetic makeup, exposure to cancer-causing agents as a result of lifestyle or occupation, and men's greater tendency to delay going to the doctor. Although the relationship of SES to cancer varies with site (for example, lung and stomach cancers are linked to lower SES, breast and prostate cancers to higher SES),

**FIGURE 15.4** Incidence of 10 leading cancer types among men and women in the United States, 2012. (From R. Siegel, K. D. Miller, & A. Jemal, 2016, "Cancer Statistics, 2016," *CA: A Cancer Journal for Clinicians*, 66, p. 11. Copyright © 2016 American Cancer Society, Inc. Reproduced with permission of Wiley, Inc.)

## Applying what we Know

### Reducing Cancer Incidence and Deaths

INTERVENTION	DESCRIPTION
Know the seven warning signs of cancer.	The signs are change in bowel or bladder habits, sore that does not heal, unusual bleeding or discharge, thickening or lump in a breast or elsewhere in your body, indigestion or swallowing difficulty, obvious change in a wart or mole, nagging cough or hoarseness. If you have any of these signs, consult your doctor immediately.
Schedule regular medical checkups and cancer-screening tests.	Women should have a mammogram and Pap test every 1 to 2 years. Beginning at age 50, men should have an annual prostate screening test. Both men and women should be screened periodically for colon cancer, as recommended by their doctor.
Avoid tobacco.	Cigarette smoking causes 90 percent of lung cancer deaths and 30 percent of all cancer deaths. Smokeless (chewing tobacco increases risk of cancers of the mouth, larynx, throat, and esophagus.
Limit alcohol consumption.	Consuming more than one drink per day for women or two drinks per day for men increases risk of cancers of the breast, kidney, liver, head, and neck.
Avoid excessive sun exposure.	Sun exposure causes many cases of skin cancer. When in the sun for an extended time, wear sunglasses, use sunscreen that protects against both UVA and UVB rays, and cover exposed skin.
Avoid unnecessary X-ray exposure.	Excessive exposure to X-rays increases risk of many cancers. Most medical X-rays are adjusted to deliver the lowest possible dose but should not be used unnecessarily.
Avoid exposure to industrial chemicals and other pollutants.	Exposure to nickel, chromate, asbestos, vinyl chloride, radon, and other pollutants increases risk of various cancers.
Weigh the benefits versus risks of hormone therapy.	Because estrogen replacement increases risk of uterine and breast cancers, carefully consider hormone therapy with your doctor.
Maintain a healthy diet.	Eating vegetables, fruits, and whole grains, while avoiding excess dietary fat and salt-cured, smoked, and nitrite-cured foods, reduces risk of colon and rectal cancers.
Avoid excessive weight gain.	Overweight and obesity increase risk of many cancers, including of the breast, colon, esophagus, kidney, pancreas, and uterus.
Adopt a physically active lifestyle.	Physical activity offers protection against cancers at all body sites except the skin, with the strongest evidence for cancers of the breast, rectum, and colon.

Source: American Cancer Society, 2015a.

cancer death rates increase sharply as SES decreases and are especially high among African Americans (Fernandes-Taylor & Bloom, 2015). Poorer medical care and reduced ability to fight the disease due to factors associated with poverty, including high life stress, inadequate diet, and co-occurrence of other illnesses, are responsible. Consequently, although African Americans have a lower incidence of breast cancer than European Americans, the African-American breast cancer death rate is higher.

Overall, a complex interaction of heredity, biological aging, and environment contributes to cancer. For example, many patients with familial breast cancer who respond poorly to treatment have defective forms of particular tumor-suppressor genes (either BRCA1 or BRCA2). Women with these mutations are especially likely to develop early-onset breast cancer, before age 40 (Haley, 2016). But their risk remains elevated throughout middle and late adulthood, when breast cancer rises among women in general. Genetic screening is available, permitting prevention efforts to begin early. Nevertheless, breast cancer susceptibility genes account for only 5 to 10 percent of all cases; most women with breast cancer do not have a family history

(American Cancer Society, 2015b). Other genes and lifestyle factors—including alcohol consumption, overweight, physical inactivity, never having had children, use of oral contraceptives, and hormone therapy to treat menopausal symptoms—heighten the risk.

People often fear cancer because they believe it is incurable. Yet 60 percent of affected individuals are cured—free of the disease for five years or longer. Survival rates, however, vary widely with type of cancer (Siegel, Miller, & Jemal, 2016). For example, they are relatively high for breast and prostate cancers, intermediate for uterine and colon cancers, and low for lung and pancreatic cancers.

Breast cancer is the leading malignancy for women, prostate cancer for men. Lung cancer ranks second for both genders; it causes more deaths (largely preventable through avoiding tobacco) than any other cancer type. It is followed closely by colon and rectal cancer. Scheduling annual medical checkups that screen for these and other forms of cancer and taking the additional steps listed in Applying What We Know above can reduce cancer illness and death rates considerably. An increasing

## Applying what we Know

### Reducing the Risk of Heart Attack

INTERVENTION	RISK REDUCTION
Quit smoking.	Five years after quitting, nonsmokers show a greatly reduced risk compared to current smokers. Chemicals in tobacco damage the heart and blood vessels and greatly increase the risk of atherosclerosis.
Reduce blood cholesterol level.	Reductions in cholesterol average 10 percent with transition to a healthy diet.
Treat high blood pressure.	A combination of healthy diet and drug therapy can lower blood pressure substantially. When allowed to persist, high blood pressure places added force against the artery walls, damaging them.
Maintain ideal weight.	Greatly reduced risk for people who maintain ideal body weight compared to those who are obese.
Exercise regularly.	Greatly reduced risk for people who maintain an active rather than a sedentary lifestyle. In addition to contributing to healthy weight, lowers cholesterol and blood pressure and helps prevent type 2 diabetes, which is strongly linked to heart disease.
Drink an occasional glass of wine or beer. <sup>a</sup>	Modestly reduced risk for people who consume small-to-moderate amounts of alcohol. Believed to promote high-density lipoproteins (a form of “good cholesterol” that lowers “bad cholesterol”) and to prevent clot formation.
If medically recommended, take low-dose aspirin.	Modestly reduced risk for people with a previous heart attack or stroke, by lowering the likelihood of blood clots (should be doctor advised; long-term use can have serious side effects).
Reduce hostility and other forms of psychological stress.	People under stress are more likely to engage in high-risk behaviors, such as overeating and smoking, and to display high-risk symptoms, such as high blood pressure.

<sup>a</sup>Recall from Chapter 13 that heavy alcohol use increases the risk of cardiovascular disease as well as many other diseases.

Source: Mozaffarian et al., 2016.

number of cancer-promoting mutations are being identified, and promising new therapies targeting these genes are being tested.

Surviving cancer is a triumph, but it also brings emotional challenges. During cancer treatment, relationships focus on the illness. Afterward, they must refocus on health and full participation in daily life. Unfortunately, stigmas associated with cancer exist (Daher, 2012). Friends, family, and co-workers may need reminders that cancer is not contagious and that with patience and support from supervisors and co-workers, cancer survivors regain their on-the-job productivity.

**Cardiovascular Disease.** Despite a decline over the last few decades (see Chapter 13), each year about 25 percent of middle-aged Americans who die succumb to cardiovascular disease (Heron, 2015). We associate cardiovascular disease with heart attacks, but Devin, like many middle-aged and older adults, learned of the condition during an annual checkup. His doctor detected high blood pressure, high blood cholesterol, and *atherosclerosis*—a buildup of plaque in his coronary arteries, which encircle the heart and provide its muscles with oxygen and nutrients. These indicators of cardiovascular disease are known as “silent killers” because they often have no symptoms.

When symptoms *are* evident, they take different forms. The most extreme is a *heart attack*—blockage of normal blood supply to an area of the heart, usually brought on by a blood clot in one or more plaque-filled coronary arteries. Intense pain results as muscle in the affected region dies. A heart attack is a medical emergency; over 50 percent of victims die before reaching the hospital, another 15 percent during treatment, and an additional

15 percent over the next few years (Mozaffarian et al., 2016). Among other, less extreme symptoms of cardiovascular disease are *arrhythmia*, or irregular heartbeat. When it persists, it can prevent the heart from pumping enough blood and result in faintness. It can also allow clots to form within the heart’s chambers, which may break loose and travel to the brain. In some individuals, indigestion-like pain or crushing chest pain, called *angina pectoris*, reveals an oxygen-deprived heart.

Today, cardiovascular disease can be treated in many ways—including coronary bypass surgery, medication, and pacemakers to regulate heart rhythm. To relieve arterial blockage, Devin had *angioplasty*, a procedure in which a surgeon threaded a needle-thin catheter into his arteries and inflated a balloon at its tip, which flattened fatty deposits to allow blood to flow more freely. Unless Devin took other measures to reduce his risk, his doctor warned, the arteries would clog again within a year. As Applying What We Know above indicates, adults can do much to prevent heart disease or slow its progress.

Some risks, such as heredity, advanced age, and being male, cannot be changed. But cardiovascular disease is so disabling and deadly that people must be alert for it where they least expect it—for example, in women. Because men account for over 70 percent of cases in middle adulthood, doctors often view a heart attack as a “male problem” and frequently overlook women’s unique symptoms. Rather than chest pain, many women experience extreme fatigue, dizziness, palpitations, pain in the upper back or arm, as well as intense anxiety—symptoms often mistaken for a panic attack. Women themselves are less likely to recognize symptoms and, therefore, often delay in seeking help.

In follow-ups of victims of heart attacks, women—especially African-American women, who are at increased risk—were less likely to be offered drugs to treat blood clots and costly, invasive therapies, such as angioplasty and bypass surgery (Mehta et al., 2016). As a result, treatment outcomes—including rehospitalization and death—tend to be worse for women, particularly black women.

**Osteoporosis.** When age-related bone loss is severe, a condition called **osteoporosis** develops. The disorder, affecting 10 percent of U.S. adults age 50 and older—amounting to 10 million people, most of whom are women—greatly magnifies the risk of bone fractures. An additional 44 percent are at risk for osteoporosis because they have bone density levels low enough to be of concern. From middle to late adulthood, osteoporosis increases fivefold in women, from 7 to 35 percent, and triples in men, from 3 to 11 percent (Wright et al., 2014). Because the bones gradually become more porous over many years, osteoporosis may not be evident until fractures—typically in the spine, hips, and wrist—occur or are discovered through X-rays.

A major factor related to osteoporosis is the drop in estrogen associated with menopause. In middle and late adulthood, women lose about 50 percent of their bone mass, about half of it in the first 10 years following menopause—a decline that, by the late sixties, is two to five times greater than in men (Drake, Clark, & Lewiecki, 2015). The earlier a woman reaches menopause, the greater her chances of developing osteoporosis related to estrogen loss. In men, the age-related decrease in testosterone—though much more gradual than estrogen loss in women—contributes to bone loss because the body converts some to estrogen.

Heredity plays an important role. A family history of osteoporosis increases risk, with identical twins more likely than fraternal twins to share the disorder (Ralston & Uitterlinden, 2010). People with thin, small-framed bodies are more likely to be affected because they typically attain a lower peak bone mass in adolescence. In contrast, higher bone density makes African Americans less susceptible than other U.S. ethnic groups (Wright et al., 2014). An unhealthy lifestyle also contributes: A diet deficient in calcium and vitamin D (essential for calcium absorption), excess intake of sodium and caffeine, and physical inactivity reduce bone mass. Cigarette smoking and alcohol consumption are also harmful because they interfere with replacement of bone cells (Drake, Clark, & Lewiecki, 2015).

When major bone fractures (such as the hip) occur, many people suffer permanent loss in function and quality of life, and they are at high risk for additional fractures. Furthermore, a serious fracture triples the chances of dying within a year (Cauley, 2013). Osteoporosis usually develops earlier in women than in men, so it has become known as a “women’s disease.” Men are far less likely to be screened and treated for it, even after a hip fracture. Compared with women, men with hip fractures tend to be older and to lack a history of interventions aimed at preserving bone density. Probably for these reasons, the one-year mortality rate after hip fracture is greater for men than for women.

To treat osteoporosis, doctors recommend a diet enriched with calcium and vitamin D, weight-bearing exercise (walking rather

A physical therapist guides this middle-aged patient through a resistance training regimen, one recommended intervention for osteoporosis. Because women are at much greater risk for the disease, men are less likely to be screened and treated.

than swimming), resistance training, and bone-strengthening medications (Drake, Clark, & Lewiecki, 2015). A better way to reduce lifelong risk is through early prevention: maximizing peak bone density by increasing calcium and vitamin D intake and engaging in regular exercise in childhood, adolescence, and early adulthood.

## Hostility and Anger

Whenever Trisha’s sister Dottie called, she seemed like a powder keg ready to erupt. Dottie was critical of her boss at work, impatient with anything that interfered with her progress at getting tasks done, intensely competitive about succeeding, and explosive when she was dissatisfied. Once, when Dottie was displeased with the way Trisha, a lawyer, had handled some family legal affairs after their father died, she angrily hurled a stream of insulting remarks: “Any lawyer knows that, Trisha. How could you be so stupid! I should have called a *real* lawyer.”

At age 53, Dottie had high blood pressure, difficulty sleeping, and back pain. In the past five years, she had been hospitalized five times—twice for treatment of digestive problems, twice for an irregular heartbeat, and once for a benign tumor on her thyroid gland. Trisha wondered whether Dottie’s personal style was partly responsible for her health problems.

That hostility and anger might have negative effects on health is a centuries-old idea. Several decades ago, researchers first tested this notion by identifying 35- to 59-year-old men who displayed the **Type A behavior pattern**—extreme competitiveness, ambition, impatience, hostility, angry outbursts, and sense of eagerness, hurriedness, and time pressure. They found that within the next eight years, Type As were more than twice as likely as Type Bs (people with a more relaxed disposition) to develop heart disease (Rosenman et al., 1975).

Later studies, however, often failed to confirm these outcomes. Type A is actually a mix of behaviors, only one or two of which affect health. Current evidence pinpoints hostility as a

“toxic” ingredient of Type A, since isolating it from global Type A consistently predicts heart disease and other health problems, even after factors that might otherwise account for these outcomes—such as smoking, alcohol consumption, overweight, and life stressors—are controlled (Eaker et al., 2004; Matthews et al., 2004; Smith et al., 2004; Smith & Mackenzie, 2006). The risks of high blood pressure, atherosclerosis, and stroke are several times greater in adults scoring high on hostility measures than in those scoring low (Räikkönen et al., 2004; Yan et al., 2003).

*Expressed hostility* in particular—frequent angry outbursts; rude, disagreeable behavior; critical and condescending nonverbal cues during social interaction, including glares; and expressions of contempt and disgust—predicts greater cardiovascular arousal, coronary artery plaque buildup, and heart disease (Haukkala et al., 2010; Smith & Cundiff, 2011; Smith et al., 2012). A related feature of the Type A pattern that also predicts heart disease is a socially dominant interactive style, evident in rapid, loud insistent speech and impatiently cutting off and talking over others (Smith, 2006). As people engage in these behaviors, heart rate, blood pressure, and stress hormones escalate.

Type A individuals become increasingly recognizable during the busiest years of career achievement. In a Finnish study tracking a nationally representative sample of several thousand participants, Type A behavior intensified from adolescence into the mid-thirties, followed by only a slight decline into the mid-forties (Hinsta et al., 2014). As the Type A pattern becomes clearly evident, age-related risk of heart disease rises.

Can Dottie preserve her health by bottling up her hostility instead of expressing it? Repeatedly suppressing overt anger or ruminating about past anger-provoking events is also associated with high blood pressure and heart disease (Eaker et al., 2007; Hogan & Linden, 2004). A better alternative, as we will see, is to develop effective ways of handling stress and conflict.

## Adapting to the Physical Challenges of Midlife

**15.6** Discuss the benefits of stress management, exercise, and hardiness in dealing effectively with the physical challenges of midlife.

**15.7** Explain the double standard of aging.

Middle adulthood is often a productive time of life, when people attain their greatest accomplishments and satisfactions. Nevertheless, it takes considerable stamina to cope with the full array of changes this period can bring. Devin responded to his expanding waistline and cardiovascular symptoms by leaving his desk twice a week to attend a low-impact aerobics class and by reducing work-related stress through daily 10-minute meditation sessions. Aware of her sister Dottie’s difficulties, Trisha resolved to handle her own angry and impatient feelings more adaptively. And her generally optimistic outlook enabled her to cope successfully with the physical changes of midlife, the pressures of her legal career, and Devin’s cardiovascular disease.

## Stress Management

Turn back to Chapter 13, page 455, and review the negative consequences of psychological stress on the cardiovascular, immune, and gastrointestinal systems. As adults encounter problems at home and at work, daily hassles can add up to a serious stress load. Stress management is important at any age, but in middle adulthood it can limit the age-related rise in illness and, when disease strikes, reduce its severity.

Applying What We Know on the following page summarizes effective ways to reduce stress. Even when stressors cannot be eliminated, people can change how they handle some and view others. At work, Trisha focused on problems she could control—not on her boss’s irritability but on ways to delegate routine tasks to her staff so she could concentrate on challenges that required her knowledge and skills. When Dottie phoned, Trisha learned to distinguish normal emotional reactions from unreasonable self-blame. Instead of interpreting Dottie’s anger as a sign of her own incompetence, she reminded herself of Dottie’s difficult temperament and hard life. And greater life experience helped her accept change as inevitable, so that she was better-equipped to deal with the jolt of sudden events, such as Devin’s hospitalization for treatment of heart disease.

Notice how Trisha called on two general strategies for coping with stress, discussed in Chapter 10: (1) *problem-centered coping*, in which she appraised the situation as changeable, identified the difficulty, and decided what to do about it; and (2) *emotion-centered coping*, which is internal, private, and aimed at controlling distress when little can be done about a situation. Research reveals that adults who effectively reduce stress move flexibly between problem-centered and emotion-centered techniques, depending on the situation (Zakowski et al., 2001). Their approach is deliberate, thoughtful, and respectful of both themselves and others.

Notice, also, that problem-focused and emotion-focused coping, though they have different immediate goals, facilitate each other. Effective problem-focused coping reduces emotional

Stress management in middle adulthood helps limit the age-related rise in illness. This midlifer reduces stress by periodically leaving his high-pressure office environment to work in a sunny, relaxing space.

## Applying what we Know

### Managing Stress

STRATEGY	DESCRIPTION
Reevaluate the situation.	Learn to differentiate appropriate reactions from those based on irrational beliefs.
Focus on events you can control.	Don't worry about things you cannot change or that may never happen; focus on strategies for handling events under your control.
View life as fluid.	Expect change and accept it as inevitable; then many unanticipated changes will have less emotional impact.
Consider alternatives.	Don't rush into action; think before you act.
Set reasonable goals for yourself.	Aim high, but be realistic about your capacities, motivation, and the situation.
Exercise regularly.	A physically fit person can better handle stress, both physically and emotionally.
Master relaxation techniques.	Relaxation helps refocus energies and reduce the physical discomfort of stress. Classes and self-help books teach these techniques.
Use constructive approaches to anger reduction.	Delay responding ("Let me check into that and get back to you"); use mentally distracting behaviors (counting to 10 backwards) and self-instruction (a covert "Stop!") to control anger arousal; then engage in calm, self-controlled problem solving ("I should call him rather than confront him personally").
Seek social support.	Friends, family members, co-workers, and organized support groups can offer information, assistance, and suggestions for coping with stressful situations.

distress, while effective emotion-focused coping helps people face problems more calmly and, thus, generate better solutions. Ineffective coping, in contrast, is largely emotion-focused and self-blaming, impulsive, or escapist.

Constructive approaches to anger reduction are a vital health intervention (refer again to Applying What We Know). Teaching people to be assertive rather than hostile and to negotiate rather than explode interrupts the intense physiological response that intervenes between psychological stress and illness. Sometimes it is best to delay responding by simply leaving a provocative situation, taking time to think through how to handle it.

As noted in Chapter 13, people tend to cope with stress more effectively as they move from early to middle adulthood. They may become more realistic about their ability to change situations and more skilled at anticipating stressful events and at preparing to manage them (Aldwin, Yancura, & Boeninger, 2010). Furthermore, when middle-aged adults surmount a highly stressful experience, they often report lasting personal benefits as they look back with amazement at what they were able to accomplish under extremely trying conditions. A serious illness and brush with death commonly bring changes in values and perspectives, such as clearer life priorities, a greater sense of personal strength, and closer ties to others. Interpreting trauma as growth-promoting is related to more effective coping with current stressors and with increased physical and mental health years later (Aldwin & Yancura, 2011; Proulx & Aldwin, 2016). In this way, managing intense stress can serve as a context for positive development.

But for people who do have difficulty handling midlife's challenges, communities provide fewer social supports than for younger or older adults. For example, Jewel had little knowledge

of what to expect during the climacteric. "It would have helped to have a support group so I could have learned about menopause and dealt with it more easily," she told Trisha. Community programs addressing typical midlife concerns, such as those of adult learners returning to college and caregivers of aging parents, can reduce stress during this period.

### LOOK and LISTEN

Interview a middle-aged adult who has overcome a highly stressful experience, such as a serious illness, about how he or she coped. Inquire about any resulting changes in outlook on life. Do the adult's responses fit with research findings?

### Exercise

Regular exercise, as noted in Chapter 13, has a range of physical and psychological benefits—among them, equipping adults to handle stress more effectively and reducing the risk of many diseases. Heading for his first aerobics class, Devin wondered, Can starting to exercise at age 50 counteract years of physical inactivity? To shed light on this question, researchers combined six longitudinal studies in which 660,000 European and U.S. adults, ranging in age from 21 to 98 years, were asked about how much time they typically devote to various leisure-time physical activities each week. The greater participants' weekly energy expenditure through physically active pursuits, the lower their chances of dying during the following 14 years (Arem et al., 2015). And compared with no activity, any amount of exercise had longevity

benefits, even after many factors—such as SES, health status, alcohol and tobacco use, and BMI—that might account for the findings were controlled.

Yet more than half of U.S. middle-aged adults are sedentary. Furthermore, many who begin an exercise program discontinue it within the first six months. Even among those who stay active, fewer than 18 percent engage in the nationally recommended levels of leisure-time physical activity and resistance exercises (see page 448 in Chapter 13) (U.S. Department of Health and Human Services, 2015d).

A person beginning to exercise in midlife must overcome initial barriers and ongoing obstacles—lack of time and energy, inconvenience, work conflicts, and health factors (such as overweight). *Self-efficacy*—belief in one’s ability to succeed—is just as vital in adopting, maintaining, and exerting oneself in an exercise regimen as it is in career progress (see Chapter 14). An important outcome of starting an exercise program is that sedentary adults gain in self-efficacy, which further promotes physical activity (McAuley & Elavsky, 2008; Parschau et al., 2014). Enhanced physical fitness, in turn, prompts middle-aged adults to feel better about their physical selves. Over time, their physical self-esteem—sense of body conditioning and attractiveness—rises (Elavsky & McAuley, 2007; Gothe et al., 2011).

A variety of group and individualized approaches are successful in increasing middle-aged adults’ physical activity. Among these are workplace-based programs offering rewards for reaching exercise goals and web or mobile-phone-based interventions with tools for goal setting, self-monitoring, and feedback on progress (Duncan et al., 2014; Morgan et al., 2011). One

© BLEND IMAGES/ALAMY

In cities across the United States, barriers to physical activity are being overcome through the creation of attractive, safe parks and trails. But low-SES adults need greater access to convenient, pleasant exercise environments.

innovative program focused on middle-aged adults who had been active in sports as youths but had disengaged from physical activity. Relative to controls, those who viewed a short video on the diverse benefits of adult team sports (such as health, skill gains, and likeminded friendships) attached greater value to becoming a sports participant in their hoped-for self-images (Lithopoulos, Rathwell, & Young, 2015). As Chapter 18 will reveal, future-oriented self-descriptions are good predictors of midlife behavior change.

Accessible, attractive, and safe exercise environments—parks, walking and biking trails, and community recreation centers—and frequent opportunities to observe others using them also promote physical activity. Besides health problems and daily stressors, low-SES adults often mention inconvenient access to facilities, expense, unsafe neighborhoods, and unclean streets as barriers to exercise—important reasons that activity level declines sharply with SES (Taylor et al., 2007; Wilbur et al., 2003). Interventions aimed at increasing physical activity among low-SES adults must address these issues in addition to lifestyle and motivational factors.

## Hardiness

What type of individual is likely to cope adaptively with stress brought on by the inevitable changes of life? Researchers interested in this question have identified a set of three personal qualities—control, commitment, and challenge—that, together, they call **hardiness** (Maddi, 2007, 2011, 2016). Together, the three hardiness attributes motivate people to try their best to turn life’s stressors into opportunities for resilience.

Trisha fit the pattern of a hardy individual. First, she regarded most experiences as *controllable*. “You can’t stop all bad things from happening,” she advised Jewel after hearing about her menopausal symptoms, “but you can try to do something about them.” Second, Trisha displayed a *committed*, involved approach to daily activities, finding meaning in almost all of them, even during stressful times. Finally, she viewed stressful changes as *challenges*—as occasions for learning and self-improvement.

Hardiness influences the extent to which people appraise stressful situations as manageable, interesting, even enjoyable. These optimistic appraisals, in turn, predict health-promoting behaviors, tendency to seek social support, reduced physiological arousal to stress, and fewer physical and emotional symptoms (Maddi, 2006; Maruta et al., 2002; Rääkkönen et al., 1999; Smith, Young, & Lee, 2004). Furthermore, high-hardy individuals are likely to use active, problem-centered coping strategies in situations they can control. In contrast, low-hardy people more often use emotion-centered and avoidant coping strategies—for example, saying, “I wish I could change how I feel” or eating and drinking to distract themselves from the stressful event (Maddi, 2007; Soderstrom et al., 2000).

In this and previous chapters, we have seen that many factors act as stress-resistant resources—among them heredity, diet, exercise, social support, and coping strategies. Research on hardiness emphasizes an additional ingredient: a generally optimistic

## Social Issues: Health

### The Silver Lining in Life's Adversities

Many adults, in recounting a difficult time in their lives, say that ultimately it made them stronger—an outcome confirmed by research. As long as serious adversity is not frequent and overwhelming, it can lead to remarkable personal benefits.

In a study carried out in France, researchers followed a nationally representative sample of 2,000 adults, ranging in age from 18 to 101, for four years (Seery, Holman & Silver, 2010). To assess *lifetime exposure to adversity*, participants were given a list of 37 negative life events and asked to indicate which ones they had experienced, how often, and the age at which each had occurred. The list focused on serious stressors—for example, violent assault, death of a loved one, severe financial difficulties, divorce, and major disasters such as fire, flood, or earthquake.

A year later, the researchers returned for a measure of *recent exposure to adversity*, asking participants to indicate how many negative life events they had experienced in the previous six months. Finally, once each year, participants' mental health and well-being were assessed.

Findings revealed that adults with a history of modest lifetime adversity exposure, compared to no adversity or high adversity, reported more favorable adjustment—less overall psychological distress, less functional impairment (compromised work and social

activities due to poor physical and mental health), fewer post-traumatic stress symptoms, and greater life satisfaction (see Figure 15.5). Furthermore, people with modest lifetime adversity were less negatively affected by exposure to recent adversity. These outcomes remained after controlling for diverse factors that might influence experiences of adversity, including age, gender, ethnicity, marital status, SES, and physical health.

Experiencing modest levels of lifetime adversity seems to foster a sense of mastery, generating in people the hardiness, or toughness, needed to overcome future stressors (Mineka & Zinbarg, 2006). Adults with no history of adversity are deprived of vital opportunities for learning to manage life stressors, so they respond less optimally when faced with them. And high levels of lifetime adversity overtax people's coping skills, engulfing them with feelings of hopelessness and loss of control

and interfering substantially with mental health and well-being.

In sum, having to grapple with occasional adverse life events is a vital source of resilience. It fortifies people with the personal attributes they need to surmount life stressors they are almost certain to encounter in the future.

**FIGURE 15.5** Relationship of lifetime adversity to mental health and life satisfaction. Among a large, nationally representative sample of French adults, modest lifetime adversity, compared to no or high adversity, predicted reduced overall distress, functional impairment, and post-traumatic stress symptoms and greater life satisfaction. (From M. D. Seery, E. A. Holman, & R. C. Silver, 2010, "Whatever Does Not Kill Us: Cumulative Lifetime Adversity, Vulnerability, and Resilience," *Journal of Personality and Social Psychology*, 99, p. 1030. Copyright © 2010 by the American Psychological Association. Adapted by permission.)

tic, determined, zestful approach to life. See the Social Issues: Health box above for research suggesting that experiencing a modest level of adversity can actually be life-enriching, perhaps because it promotes hardiness.

### Gender and Aging: A Double Standard

Negative stereotypes of aging, which lead many middle-aged adults to fear physical changes, are more likely to be applied to women than to men, yielding a double standard (Antonucci, Blieszner, & Denmark, 2010). Though many women in midlife say they have "hit their stride"—feel assertive, confident, versatile, and capable of resolving life's problems—people often rate them as less attractive and as having more negative personality

characteristics than middle-aged men (Denmark & Klara, 2007; Kite et al., 2005; Lemish & Muhlbauer, 2012).

The ideal of a sexually attractive woman—smooth skin, good muscle tone, lustrous hair—is the heart of the double standard of aging. The end of a woman's capacity to bear children contributes to negative judgments of physical appearance, especially by men (Marcus-Newhall, Thompson, & Thomas, 2001). Societal forces exaggerate this view. For example, middle-aged adults in media ads are usually male executives, fathers, and grandfathers—handsome images of competence and security. And the much larger array of cosmetic products and medical treatments offered to women to hide signs of aging may induce many to feel ashamed of their age and appearance (Chrisler, Barney, & Palatino, 2016).

At one time in our evolutionary history, this double standard may have been adaptive. Today, as many couples limit childbearing and devote more time to career and leisure pursuits, it has become irrelevant. Models of older women in the media and in everyday life whose days are full of intimacy, accomplishment, hope, and imagination can help create a new cultural vision of women growing older—one that emphasizes gracefulness, fulfillment, and inner strength.

## Ask yourself

**CONNECT** According to the lifespan perspective, development is multidimensional—affected by biological, psychological, and social forces. Provide examples of how this assumption characterizes health at midlife.

**APPLY** During a routine physical exam, Dr. Furrow gave 55-year-old Bill a battery of tests for cardiovascular disease but did not assess his bone density. In contrast, when 60-year-old Cara complained of palpitations and panic attacks, Dr. Furrow opted to “wait and see” before initiating further testing. What might account for Dr. Furrow’s different approaches to Bill and Cara?

**REFLECT** Which midlife health problem is of greatest personal concern to you? What steps can you take now to help prevent it?

## COGNITIVE DEVELOPMENT

In middle adulthood, the cognitive demands of everyday life extend to new and sometimes more challenging situations. Consider a typical day in the lives of Devin and Trisha. Recently appointed dean of faculty at a small college, Devin was at his desk by 7:00 a.m. In between strategic-planning meetings, he reviewed files of applicants for new positions, worked on the coming year’s budget, and spoke at an alumni luncheon. Meanwhile, Trisha prepared for a civil trial, participated in jury selection, and then joined other top lawyers at her firm for a conference about management issues. That evening, Trisha and Devin advised their 20-year-old son, Mark, who had dropped by to discuss his uncertainty over changing his college major. By 7:30 p.m., Trisha was off to an evening meeting of the local school board. And Devin left for a biweekly gathering of an amateur quartet in which he played the cello.

Middle adulthood is a time of expanding responsibilities—on the job, in the community, and at home. To juggle diverse roles effectively, Devin and Trisha called on a wide array of intellectual abilities, including accumulated knowledge, verbal fluency, memory, rapid analysis of information, reasoning, problem solving, and expertise in their areas of specialization. What changes in thinking take place in middle adulthood? How does vocational life—a major arena in which cognition is expressed—influence intellectual skills? And what can be done to support the rising tide of adults who are returning to higher education in hopes of enhancing their knowledge and quality of life?

## Changes in Mental Abilities

**15.8** Describe cohort effects on intelligence revealed by Schaie’s Seattle Longitudinal Study.

**15.9** Describe changes in crystallized and fluid intelligence in middle adulthood, and discuss individual and group differences in intellectual development.

At age 50, when he occasionally couldn’t recall a name or had to pause in the middle of a lecture or speech to think about what to say next, Devin wondered, Are these signs of an aging mind? Twenty years earlier, he had taken little notice of the same events. His questioning stems from widely held stereotypes of older adults as forgetful and confused. Most cognitive aging research has focused on deficits while neglecting cognitive stability and gains.

As we examine changes in thinking in middle adulthood, we will revisit the theme of diversity in development. Different aspects of cognitive functioning show different patterns of change. Although declines occur in some areas, most people display cognitive competence, especially in familiar contexts, and some attain outstanding accomplishment. As we will see, certain apparent decrements in cognitive aging result from weaknesses in the research itself! Overall, the evidence supports an optimistic view of adult cognitive potential.

The research we are about to consider illustrates core assumptions of the lifespan perspective: development as *multidimensional*, or the combined result of biological, psychological, and social forces; development as *multidirectional*, or the joint expression of growth and decline, with the precise mix varying across abilities and individuals; and development as *plastic*, or open to change, depending on how a person’s biological and environmental history combines with current life conditions.

## Cohort Effects

Research using intelligence tests sheds light on the widely held belief that intelligence inevitably declines in middle and late adulthood as the brain deteriorates. Many early cross-sectional studies showed this pattern—a peak in performance at age 35 followed by a steep drop into old age. But widespread testing of college students and soldiers in the 1920s provided a convenient opportunity to conduct longitudinal research, retesting participants in middle adulthood. These findings revealed an age-related increase! To explain this contradiction, K. Warner Schaie (1998, 2005, 2016) used a sequential design, combining longitudinal and cross-sectional approaches (see page 36 in Chapter 1) in the Seattle Longitudinal Study.

In 1956, people ranging in age from 22 to 70 were tested cross-sectionally. Then, at regular intervals, longitudinal follow-ups were conducted and new samples added, yielding a total of 6,000 participants, five cross-sectional comparisons, and longitudinal data spanning more than 60 years. Findings on five

**FIGURE 15.6** Cross-sectional and longitudinal trends in verbal ability, illustrating cohort effects. The steep cross-sectional decline is largely due to better health and education in younger generations. When adults are followed longitudinally, their verbal scores rise during early and middle adulthood and gradually decline during later years. However, this longitudinal trend does not hold for all abilities. (From K. W. Schaie, 1988, “Variability in Cognitive Functioning in the Elderly,” in M. A. Bender, R. C. Leonard, & A. D. Woodhead [Eds.], *Phenotypic Variation in Populations*, p. 201. Adapted with kind permission from Springer Science+Business Media B. V. and K. W. Schaie.)

mental abilities showed the typical cross-sectional drop after the mid-thirties. But longitudinal trends for those abilities revealed modest gains in midlife, sustained into the fifties and the early sixties, after which performance decreased gradually.

Figure 15.6 illustrates Schaie’s cross-sectional and longitudinal outcomes for just one intellectual factor: verbal ability. How can we explain the seeming contradiction in findings? *Cohort effects* are largely responsible for this difference. In cross-sectional research, each new generation experienced better health and education and more cognitively stimulating everyday experiences than the one before it (Schaie, 2013). Also, the tests given may tap abilities less often used by older individuals, whose lives no longer require that they learn information for its own sake but, instead, skillfully solve real-world problems.

## Crystallized and Fluid Intelligence

A close look at diverse mental abilities shows that only certain ones follow the longitudinal pattern identified in Figure 15.6. To appreciate this variation, let’s consider two broad mental abilities, each of which includes an array of specific intellectual factors.

The first of these broad abilities, **crystallized intelligence**, refers to skills that depend on accumulated knowledge and experience, good judgment, and mastery of social conventions—abilities acquired because they are valued by the individual’s culture. Devin made use of crystallized intelligence when he expressed

himself articulately at the alumni luncheon and suggested effective ways to save money in budget planning. On intelligence tests, vocabulary, general information, verbal comprehension, and logical reasoning items measure crystallized intelligence.

In contrast, **fluid intelligence** depends more heavily on basic information-processing skills—ability to detect relationships among visual stimuli, speed of analyzing information, and capacity of working memory. Though fluid intelligence often combines with crystallized intelligence to support effective reasoning and problem solving, it is believed to be influenced less by culture than by conditions in the brain and by learning unique to the individual (Horn & Noll, 1997). Intelligence test items reflecting fluid abilities include spatial visualization, digit span, letter-number sequencing, and symbol search. (Refer to page 315 in Chapter 9 for examples.)

Many cross-sectional studies show that crystallized intelligence increases steadily through middle adulthood, whereas fluid intelligence begins to decline in the twenties. These trends have been found repeatedly in investigations in which younger and older participants had similar education and general health status, largely correcting for cohort effects (Hartshorne & Germine, 2015; Miller et al., 2009; Park et al., 2002). In one such investigation, including nearly 2,500 mentally and physically healthy 16- to 85-year-olds, verbal (crystallized) IQ peaked between ages 45 and 54 and did not decline until the eighties! Nonverbal (fluid) IQ, in contrast, dropped steadily over the entire age range (Kaufman, 2001).

The midlife rise in crystallized abilities makes sense because adults are constantly adding to their knowledge and skills at work, at home, and in leisure activities. In addition, many crystallized skills are practiced almost daily. But does longitudinal evidence confirm the progressive falloff in fluid intelligence? And if so, how can we explain it?

AP IMAGES/THE ARIZONA DAILY SUN, JAKE BACON

Don Clarke, who flew attack helicopters in the U.S. army, fulfilled a long-held dream when he became an emergency medical service helicopter pilot. Flying search-and-rescue missions requires Clarke, in his early sixties, to make use of complex mental abilities that are at their peak in midlife.

**FIGURE 15.7 Longitudinal trends in six mental abilities, from the Seattle Longitudinal Study.** In five abilities, modest gains occurred into the fifties and early sixties, followed by gradual declines. The sixth ability—perceptual speed—decreased steadily from the twenties to the late eighties. And late in life, fluid factors (spatial orientation, numeric ability, and perceptual speed) showed greater decrements than crystallized factors (verbal ability, inductive reasoning, and verbal memory). (From K. W. Schaie, 1994, “The Course of Adult Intellectual Development,” *American Psychologist*, 49, p. 308. Copyright © 1994 by the American Psychological Association. Reprinted with permission of American Psychological Association.)

**Schaie’s Seattle Longitudinal Study.** Figure 15.7 shows Schaie’s longitudinal findings in detail. The five factors that gained in early and middle adulthood—verbal ability, inductive reasoning, verbal memory, spatial orientation, and numeric ability—include both crystallized and fluid skills. Their paths of change confirm that midlife is a time when some of the most complex mental abilities are at their peak (Schaie, 2013). According to these findings, middle-aged adults are intellectually “in their prime,” not—as stereotypes would have it—“over the hill.”

Figure 15.7 also shows a sixth ability, *perceptual speed*—a fluid skill in which participants must, for example, identify within a time limit which of five shapes is identical to a model or whether pairs of multidigit numbers are the same or different. Perceptual speed decreased from the twenties to the late eighties—a pattern that fits with a wealth of research indicating that cognitive processing slows as people get older (Schaie, 1998, 2005, 2013). Also notice in Figure 15.7 how, late in life, fluid factors (spatial orientation, numeric ability, and perceptual speed) show greater decrements than crystallized factors (verbal ability, inductive reasoning, and verbal memory). These trends have been confirmed in short-term longitudinal follow-ups of individuals varying widely in age (McArdle et al., 2002).

**Explaining Changes in Mental Abilities.** Some theorists believe that a general slowing of central nervous system functioning underlies nearly all age-related declines in cognitive

performance (Salthouse, 2006). Many studies offer at least partial support for this idea. For example, scores on speeded tasks tend to mirror the overall age-related decline in fluid-task performance (Finkel et al., 2009). Researchers have also identified other important changes in information processing, some of which may be triggered by declines in speed.

Before we turn to this evidence, let’s clarify why research reveals gains followed by stability in crystallized abilities, despite a much earlier decline in fluid intelligence, or basic information-processing skills. First, the decrease in basic processing, while substantial after age 45, may not be great enough to affect many well-practiced performances until quite late in life. Second, as we will see, adults can often compensate for cognitive limitations by drawing on their cognitive strengths. Finally, as people discover that they are no longer as good as they once were at certain tasks, they accommodate, shifting to activities that depend less on cognitive efficiency and more on accumulated knowledge. Thus, the basketball player becomes a coach, the once quick-witted salesperson a manager.

## Individual and Group Differences

The age trends just described mask large individual differences. Some adults, because of illness or unfavorable environments, decline intellectually much earlier than others. And others sustain high functioning, even in fluid abilities, at advanced ages.

Adults who use their intellectual skills seem to maintain them longer. In the Seattle Longitudinal Study, declines were delayed for people with above-average education; complex, self-directed occupations; and stimulating leisure pursuits that included reading, traveling, attending cultural events, and participating in clubs and professional organizations. People with flexible personalities, lasting marriages (especially to a cognitively high-functioning partner), and absence of cardiovascular and other chronic diseases were also likely to maintain mental abilities well into late adulthood (Schaie, 2011, 2013, 2016). And being economically well-off was linked to favorable cognitive development, undoubtedly because SES is associated with many of the factors just mentioned.

Several gender differences also emerged, consistent with those found in childhood and adolescence. In early and middle adulthood, women outperformed men on verbal tasks and perceptual speed, whereas men excelled at spatial skills (Maitland et al., 2000). Overall, however, changes in mental abilities over the adult years were remarkably similar for the two sexes, defying the stereotype that older women are less competent than older men.

Furthermore, when the baby-boom generation, mostly middle-aged, was compared with the previous generation at the same age, cohort effects were evident. On verbal memory, inductive reasoning, and spatial orientation, baby boomers performed substantially better, reflecting generational advances in education, technology, environmental stimulation, and health care (Schaie, 2013, 2016). These gains are expected to continue: Today’s children, adolescents, and adults of all ages attain higher mental test

scores than same-age individuals born a decade or two earlier—differences that are largest for fluid-ability tasks (see page 319 in Chapter 9 to review evidence on the Flynn effect).

Finally, adults who maintained higher levels of perceptual speed tended to be advantaged in other cognitive capacities. As we turn to information processing in midlife, we will pay special attention to the impact of processing speed on other aspects of cognitive functioning.

## Information Processing

**15.10** How does information processing change in midlife?

**15.11** Discuss the development of practical problem solving, expertise, and creativity in middle adulthood.

Many studies confirm that as processing speed slows, basic components of executive function decline. Yet midlife is also a time of great expansion in cognitive competence as adults apply their vast knowledge and life experience to problem solving in the everyday world.

## Speed of Processing

Devin watched with fascination as his 20-year-old son, Mark, played a computer game, responding to multiple on-screen cues in rapid-fire fashion. When Devin tried it, though he practiced over several days, his performance remained well behind Mark's. Similarly, on a family holiday in Australia, Mark adjusted quickly to driving on the left side of the road, but after a week, Trisha and Devin still felt confused at intersections, where rapid responses were needed.

These real-life experiences fit with laboratory findings. On both simple reaction-time tasks (pushing a button in response to a light) and complex ones (pushing a left-hand button to a blue light, a right-hand button to a yellow light), response time increases steadily from the early twenties into the nineties. The more complex the reaction time task, the more disadvantaged older adults are. Although the decline in speed is gradual and quite small—less than 1 second in most studies—it is nevertheless of practical significance (Dykiert et al., 2012; Nissan, Liewald, & Deary, 2013).

What causes this age-related slowing of cognitive processing? Researchers agree that changes in the brain are responsible but disagree on the precise explanation. According to one view, aging is accompanied by withering of the myelin coating on neural fibers within the cerebral cortex, leading to deteriorating neural connections, especially in the prefrontal cortex and the corpus callosum. Mounting evidence indicates that in healthy older adults, extent of myelin breakdown—appearing as small, high-intensity bright spots within fMRIs—predicts decrements in reaction time and other cognitive abilities (Lu et al., 2013; Papp et al., 2014; Salami et al., 2012).

Another approach to age-related cognitive slowing suggests that older adults experience greater loss of information as it moves through the cognitive system. As a result, the whole system must slow down to inspect and interpret the information. Imagine making a photocopy, then using it to make another copy. Each subsequent copy is less clear. Similarly, with each step of thinking, information degrades. The older the adult, the more exaggerated this effect (Myerson et al., 1990). Complex tasks, which have more processing steps, are more affected by information loss. Possibly, multiple neural changes that vary across individuals underlie such information loss and associated declines in processing speed (Hartley, 2006; Salthouse, 2011).

Processing speed predicts adults' performance on many tests of complex abilities. The slower their reaction time, the lower people's scores on tests of memory, reasoning, and problem solving, with relationships greater for fluid- than crystallized-ability items (Nissan, Liewald, & Deary, 2013; Salthouse & Madden, 2008). Indeed, as adults get older, correlations between processing speed and other cognitive performances strengthen (see Figure 15.8) (Li et al., 2004). This suggests that processing speed contributes broadly to declines in cognitive functioning, which become more widespread and pronounced with aging.

Yet as Figure 15.8 shows, processing speed correlates only moderately with older adults' performances, including fluid-ability tasks. And it is not the only major predictor of age-related cognitive changes. Other factors—declines in vision and

**FIGURE 15.8** Age-related changes in correlations of processing speed with measures of fluid and crystallized intelligence. Correlations are higher at younger and at older ages. During childhood, gains in processing speed support development of other abilities and are related to mental test performance (see Chapter 9, page 315). As people age, declines in processing speed limit many abilities, but more so for fluid than crystallized skills. Note, however, that even at the oldest ages, correlations between processing speed and other abilities are moderate. (From S.-C. Li et al., 2004, "Transformations in the Couplings Among Intellectual Abilities and Constituent Cognitive Processes Across the Life Span," *Psychological Science*, 15, p. 160. Copyright © 2004, Sage Publications. Reprinted by Permission of SAGE Publications.)

hearing and in executive function, especially working-memory capacity—also predict diverse age-related cognitive performances (Reuter-Lorenz, Festini, & Jantz, 2016; Verhaeghen, 2016). Nevertheless, processing speed, as we will see in the following sections, contributes to decrements in working memory. Still, disagreement persists over whether age-related cognitive changes have one common cause, best represented by processing speed, or multiple independent causes.

Furthermore, processing speed is a weak predictor of the skill with which older adults perform complex, familiar tasks in everyday life, which they continue to do with considerable proficiency. Devin, for example, played a Mozart quartet on his cello with great speed and dexterity, keeping up with three other players 10 years his junior. How did he manage? Compared with the others, he more often looked ahead in the score (Krampe & Charness, 2007). Using this compensatory approach, he could prepare a response in advance, thereby minimizing the importance of speed. In one study, researchers asked 19- to 72-year-olds to perform a variety of typing tasks and also tested their reaction time. Although reaction time slowed with age, typing speed did not change (Salthouse, 1984). Like Devin, older typists look further ahead in the material to be typed, anticipating their next keystrokes. Knowledge and experience can also compensate for impairments in processing speed. Devin's many years of playing the cello undoubtedly supported his ability to play swiftly and fluidly.

Because older adults find ways to compensate for cognitive slowing on familiar tasks, their reaction time is considerably better on verbal items (indicating as quickly as possible whether a string of letters forms a word) than on nonverbal items (responding to a light or other signal) (Verhaeghen & Cerella, 2008). Finally, as we will see in Chapter 17, older adults' processing speed can be improved through training, though age differences remain.

## Executive Function

As in childhood, studies of executive function in adulthood focus on how much information individuals can manipulate in working memory; the extent to which they can inhibit irrelevant information and behaviors; and the ease with which they can flexibly shift their focus of attention as the situation demands. Research confirms that all three executive function components decline with age.

From the twenties into the nineties, working memory diminishes steadily. Whether given verbal or spatial working-memory tasks, middle-aged and older adults perform less well than young adults. However, verbal working memory (for example, repeating a list of numerical digits backward) suffers much less than spatial working memory (remembering the locations of Xs, shown one at a time, in a computer-screen grid): Spatial performance declines at double the rate of verbal performance (Hale et al., 2011; Verhaeghen, 2014, 2016). As with reaction time on verbal items, verbal working memory may be better preserved because of task familiarity. Older adults have previously formed

and often used verbal representations of the to-be-manipulated information (Kalpouzos & Nyberg, 2012). The necessary spatial representations, in contrast, are far less familiar.

Declines in working memory are strongly related to the slowdown in information processing described earlier (Verhaeghen, 2014). Reduced processing speed limits the amount of information a person can focus on at once. But other components of executive function also contribute to working-memory limitations.

As adults get older, inhibition—resistance to irrelevant information and impulses—is harder (Gazzaley et al., 2005; Hasher, Lustig, & Zacks, 2007). On *continuous performance tasks*, in which participants are shown a series of stimuli on a computer screen and asked to press the space bar only after a particular sequence occurs (for example, the letter *K* immediately followed by the letter *A*), performance declines steadily from the thirties on, with older adults making more errors of commission (pressing the space bar in response to incorrect letter sequences). And when extraneous noise is introduced, errors of omission (not pressing the space bar after a *K–A* sequence) also rise with age (Mani, Bedwell, & Miller, 2005). In everyday life, inhibitory difficulties cause older adults to appear distractible—inappropriately diverted from the task at hand by a thought or a feature of the environment.

Age-related deficits in inhibition lead working memory to be cluttered with irrelevant items, thereby reducing its capacity. And with age, adults not only have greater difficulty ignoring irrelevant stimuli but find it harder to remove no longer needed items from working memory (Verhaeghen, 2012; Verhaeghen & Cerella, 2002). In other words, they become less effective at *updating* their working memories as task conditions change and certain information becomes irrelevant.

Finally, flexibly shifting one's focus of attention becomes more challenging with age and is especially evident in situations where people must divide their attention between two activities. When Trisha tried to check her e-mail inbox while talking on the phone, the speed and accuracy with which she performed

© JIM WEST/THE IMAGE WORKS

In midlife, people require more effort to stay focused on relevant information and to flexibly shift their attention between activities. Years of experience in performing several activities at once enables this high school math teacher to compensate for age-related declines in executive function.

each activity declined considerably. Consistent with Trisha's experience, laboratory research reveals that sustaining two tasks simultaneously, when at least one of the tasks is complex, becomes more challenging with age. Older adults have difficulty even when they have recently engaged in extensive practice of one of the tasks and it is therefore expected to be automatic (Maquestiaux, 2016). Though not as large, an age-related decrement also occurs in switching back and forth between mental operations within a single task, such as judging one of a pair of numbers as "odd or even" on some trials, "more or less" on others (Verhaeghen & Cerella, 2008; Wasylshyn, Verhaeghen, & Sliwinski, 2011). These declines in flexible shifting are likely affected by less effective inhibition, requiring older adults to exert more effort to stay focused on currently relevant aspects of tasks and to update that focus, as necessary.

But again, adults can compensate for these changes. People highly experienced in attending to critical information and performing several tasks at once, such as air traffic controllers and pilots, show smaller declines in inhibition and task-switching with age (Tsang & Shaner, 1998). Similarly, older adults handle two tasks proficiently when they have extensively practiced both of those activities over their lifetimes (Kramer & Madden, 2008).

Finally, practice can improve the ability to inhibit irrelevant information, divide attention between two tasks, and switch back and forth between mental operations. When older adults receive training in these skills, they improve as much as younger adults do, although training does not close the gap between age groups (Bherer et al., 2006; Erickson et al., 2007; Kramer, Hahn, & Gopher, 1998).

## Memory Strategies

Memory is crucial for all aspects of information processing—an important reason that we place great value on a good memory in middle and late adulthood. But older adults' ability to recall studied information is impaired relative to younger adults', a change affected by a decline in use of memory strategies. Older individuals rehearse less than younger individuals—a difference believed to be affected by a slower rate of thinking, in that older people cannot repeat new information to themselves as quickly as younger people. A reduction in working-memory capacity is another influence, leading to difficulties in retaining to-be-remembered items and processing them at the same time (Basak & Verhaeghen, 2011).

Memory strategies of organization and elaboration, which require people to link incoming information with already stored information, are also applied less often and less effectively with age (Hertzog et al., 2010; Troyer et al., 2006). An additional reason older adults are less likely to use these techniques is that they find it harder to retrieve information from long-term memory that would help them recall. For example, given a list of words containing *parrot* and *blue jay*, they don't immediately access the category "bird," even though they know it well (Hultsch et al., 1998). Why does this happen? Greater difficulty keeping one's attention on relevant information seems to be involved (Hasher,

Lustig, & Zacks, 2007). As irrelevant stimuli take up space in working memory, less is available for the memory task at hand.

But keep in mind that the memory tasks given by researchers require strategies that many adults seldom use and may not be motivated to use, since most are not in school (see Chapter 9, page 311). When a word list has a strong category-based structure, older adults organize as well as younger adults do (Naveh-Benjamin et al., 2005). And when given training in strategic memorizing, middle-aged and older people use strategies willingly, and they show improved performance over long periods, though age differences remain (Naveh-Benjamin, Brav, & Levy, 2007).

Furthermore, tasks can be designed to help older people compensate for age-related declines in working memory—for example, by slowing the pace at which information is presented or cuing the link between new and previously stored information ("To learn these words, try thinking of the category 'bird'"). In one study, adults ranging in age from 19 to 68 were shown a video and immediately tested on its content (a pressured, classroomlike condition). Then they were given a packet of information on the same topic as the video to study at their leisure and told to return three days later to be tested (a self-paced condition) (Beier & Ackerman, 2005). Performance declined with age only in the pressured condition, not in the self-paced condition. And although topic-relevant knowledge predicted better recall in both conditions, it did so more strongly in the self-paced condition, which granted participants ample time to retrieve and apply what they already knew.

## LOOK and LISTEN

Ask several adults in their fifties or early sixties to list their top three everyday memory challenges and to explain what they do to enhance recall. How knowledgeable are these midlifers about effective memory strategies?

As these findings illustrate, assessing older adults in highly structured, constrained conditions substantially underestimates what they can remember when given opportunities to pace and direct their own learning. When we consider the variety of memory skills we call on in daily life, the decrements just described are limited in scope. *Semantic memory* (general knowledge base), *procedural memory* (such as how to drive a car or solve a math problem), and memory related to one's occupation either remain unchanged or increase into midlife.

Furthermore, middle-aged people who have trouble recalling something often draw on decades of accumulated *metacognitive knowledge* about how to maximize memory—reviewing major points before an important presentation, organizing notes and files so information can be found quickly, and focusing on the most useful information to retain at the expense of less useful information. Research confirms that aging has little impact on metacognitive knowledge and the ability to apply such knowledge to improve learning (Blake & Castel, 2016; Horhota et al., 2012).

In sum, age-related changes in memory vary widely across tasks and individuals as people use their cognitive capacities to meet the requirements of their everyday worlds. Does this remind you of Sternberg's *theory of successful intelligence*, described in Chapter 9—in particular, his notion of *practical intelligence* (see page 316)? Intelligent people adapt their information-processing skills to fit with their personal desires and the demands of their environments. Therefore, to understand memory development (and other aspects of cognition) in adulthood, we must view it in context. As we turn to problem solving, expertise, and creativity, we will encounter this theme again.

## Practical Problem Solving and Expertise

One morning, Devin and Trish noticed a front-page article about their local circuit court chief justice. Elected to the bench when she turned 50, Beth had spearheaded a succession of groundbreaking programs during the previous decade. To prevent clogging of the courts with small claims, she brought judicial leaders together to create a small claims mediation program. To lessen prison overcrowding and promote recovery, she formed a criminal justice council and guided it in establishing a drug court program for nonviolent substance abusers. In lieu of a sentence, they reported to a treatment center, submitted to frequent drug testing, and met regularly with their probation officer. In these and other ways, Beth made the court system more efficient and effective, saving millions in tax dollars.

Beth's story is impressive, but many middle-aged adults display continued cognitive growth in the realm of **practical problem solving**, which requires people to size up real-world situations and analyze how best to achieve goals that have a high degree of uncertainty. Gains in *expertise*—an extensive, highly organized, and integrated knowledge base that can be used to support a high level of performance—help us understand why practical problem solving takes this leap forward.

The development of expertise is under way in early adulthood and reaches its height in midlife, leading to highly efficient and effective approaches to solving problems that are organized around abstract principles and intuitive judgments. Saturated with experience, the expert intuitively feels when an approach to a problem will work and when it will not. This rapid, implicit application of knowledge is typically the result of high ability in the domain of expertise plus years of learning, experience, and effortful practice (Krampe & Charness, 2007; Wai, 2014). It cannot be assessed by laboratory tasks or mental tests that do not call on this knowledge.

Expertise is not just the province of the highly educated and of those who rise to the top of administrative ladders. In a study of food service workers, researchers identified the diverse ingredients of expert performance in terms of physical skills (strength and dexterity); technical knowledge (of menu items, ordering, and food presentation); organizational skills (setting priorities, anticipating customer needs); and social skills (confident presen-

tation and a pleasant, polished manner). Next, 20- to 60-year-olds with fewer than two to more than ten years of experience were evaluated on these qualities. Although physical strength and dexterity declined with age, job knowledge and organizational and social skills increased (Perlmutter, Kaplan, & Nyquist, 1990). Compared to younger adults with similar years of experience, middle-aged employees performed more competently, serving customers in especially adept, attentive ways.

Midlife advantages are also evident in solutions to everyday problems (Mienaltowski, 2011; Thornton, Paterson, & Yeung, 2013). Drawing on their greater life experience, middle-aged adults are especially adept at examining everyday dilemmas from different perspectives and solving them through logical analysis. Perhaps for these reasons, midlifers are more rational everyday decision makers—less likely than younger adults, and often older adults as well, to select attractive-looking options that, on further reflection, are not the best. Consider, for example, financial decision making: In evaluating options for home and auto loans and credit cards, middle-aged adults make better choices than both their younger and older counterparts, borrowing at lower interest rates and paying lower fees—even after other relevant factors, such as credit rating and income, are controlled (Agarwal et al., 2007).

## Creativity

As noted in Chapter 13, creative accomplishment tends to peak in the late thirties or early forties and then decline, but with considerable variation across individuals and disciplines. Some people produce highly creative works in later decades: In her early sixties, Martha Graham choreographed *Clytemnestra*, recognized as one of the great full-length modern-dance dramas. Igor Stravinsky composed his last major musical work at age 84. Charles Darwin finished *On the Origin of Species* at age 50 and

FLORIAN KOPP/NEWS.COM

Middle-aged adults may experience a decrease in creative output, but their creativity often becomes more deliberately thoughtful. This glassblower produces handcrafted works of art involving multiple steps, great patience, and technical precision.

continued to write groundbreaking books and papers in his sixties and seventies. Harold Gregor, who painted the dazzling image on the cover of this book, continues to invent new styles and to be a highly productive artist at age 87. And as with problem solving, the *quality* of creativity may change with advancing age—in at least three ways.

First, youthful creativity in literature and the arts is often spontaneous and intensely emotional, while creative works produced after age 40 often appear more deliberately thoughtful. Perhaps for this reason, poets produce their most frequently cited works at younger ages than do authors of fiction and nonfiction (Kozbelt, 2016; Lubart & Sternberg, 1998). Poetry depends more on language play and “hot” expression of feelings, whereas story- and book-length works require extensive planning and molding.

Second, with age, many creators shift from generating unusual products to combining extensive knowledge and experience into unique ways of thinking (Sasser-Coen, 1993). Creative works by older adults more often sum up or integrate ideas. Mature academics typically devote less energy to new discoveries in favor of writing memoirs, histories of their field, and other reflective works. And in older creators’ novels, scholarly writings, and commentaries about their paintings and musical compositions, learning from life experience and living with old age are common themes (Lindauer, Orwoll, & Kelley, 1997; Sternberg & Lubart, 2001).

Finally, creativity in middle adulthood frequently reflects a transition from a largely egocentric concern with self-expression to more altruistic goals (Tahir & Gruber, 2003). As the middle-aged person overcomes the youthful illusion that life is eternal, the desire to give to humanity and enrich the lives of others increases.

Taken together, these changes may contribute to an overall decline in creative output in later decades. In reality, however, creativity takes new forms.

## Information Processing in Context

Cognitive gains in middle adulthood are especially likely in areas involving experience-based buildup and transformation of knowledge and skills. As the evidence just reviewed confirms, processing speed varies with the situation. When given challenging real-world problems related to their expertise, middle-aged adults are likely to win out in both efficiency and excellence of thinking. Furthermore, on tasks and test items relevant to their real-life endeavors, intelligent, cognitively active midlifers respond as competently and nearly as quickly as their younger counterparts do!

By middle age, people’s past and current experiences vary enormously—more so than in previous decades—and thinking is characterized by an increase in specialization as people branch out in various directions. Yet to reach their cognitive potential, adults must have opportunities for continued growth. Let’s see how vocational and educational environments can support cognition in midlife.

## Ask yourself

**CONNECT** In which aspects of cognition do middle-aged adults typically decline, and in which do they gain? How do those changes reflect assumptions of the lifespan perspective?

**APPLY** Asked about hiring middle-aged sales personnel, a department store manager replied, “They’re my best employees!” Why does this manager find older employees desirable, despite age-related declines in processing speed and executive function?

## Vocational Life and Cognitive Development

**15.12** Describe the relationship between vocational life and cognitive development.

Vocational settings are vital contexts for maintaining previously acquired skills and learning new ones. Yet work environments vary in the degree to which they are cognitively stimulating and promote autonomy. And inaccurate, negative stereotypes of age-related problem-solving and decision-making skills can result in older employees being assigned less challenging work.

Recall from Chapter 13 that personality characteristics, including preference for certain cognitive activities, influence occupational choice. Once a person is immersed in a job, it influences cognition. In a study of a large sample of U.S. men in diverse occupations, researchers asked about the complexity and self-direction of their jobs. During the interview, they also assessed cognitive flexibility, based on logical reasoning, awareness of both sides of an issue, and independence of judgment. Two decades later, the job and cognitive variables were remeasured, permitting a look at their effects on each other (Schooler, Mulatu, & Oates, 2004). Findings revealed that complex work augmented later cognitive flexibility more than cognitive flexibility influenced preference for complex work.

Similar findings emerged in large-scale studies carried out in Japan and Poland—cultures quite different from the United States (Kohn, 2006; Kohn et al., 1990). In each nation, having a stimulating, nonroutine job helped explain the relationship between SES and flexible, abstract thinking. Furthermore, people in their fifties and early sixties benefit cognitively from challenging work just as much as those in their twenties and thirties (Avolio & Sosik, 1999; Miller, Slomczynski, & Kohn, 1985).

Mentally stimulating work requires middle-aged and older adults to grapple with novel situations. Continuously confronting complex, novel tasks predicts gains in cognitive flexibility and reduces the age-related decline in fluid abilities, with these effects extending for a decade or more after retirement (Bowen, Noack, & Staudinger, 2011; Fisher et al., 2014). And in an investigation of World War II veterans, those scoring lower in IQ in early adulthood derived greater long-term benefits from an intellectually demanding work life (Potter, Helms, & Plassman,

2008). Compared to their higher-IQ age mates, they showed a stronger positive association between stimulating work and cognitive performance after retiring.

Once again, we are reminded of the plasticity of development. Cognitive flexibility is responsive to work experiences well into middle adulthood and perhaps beyond. Designing jobs to promote intellectual stimulation and challenge may be a powerful means of fostering higher cognitive functioning later in the lifespan.

## Adult Learners: Becoming a Student in Midlife

**15.13** Discuss the challenges that adults face in returning to college, ways to support returning students, and benefits of earning a degree in midlife.

Adults are returning to undergraduate and graduate study in record numbers. During the past three decades, students age 25 and older in U.S. colleges and universities increased from 27 to 40 percent of total enrollment, with an especially sharp rise in those over age 35 (U.S. Department of Education, 2015). Life transitions often trigger a return to formal education, as with Devin and Trisha's friend Anya, who entered a nursing program after her last child left home. Early marriage (which often disrupts women's educational pathways), divorce, widowhood, a job layoff, a return from military service, a family move, a youngest child reaching school age, older children entering college, and rapid changes in the job market are other events that commonly precede reentry (Hostetler, Sweet, & Moen, 2007; Lorentzen, 2014).

### Characteristics of Returning Students

Nearly 60 percent of adult learners are women (U.S. Department of Education, 2015). As Anya's concerns about being able to handle class work suggest (see page 507), many reentry women report feeling self-conscious, inadequate, and hesitant to talk in class. Their anxiety stems partly from not having practiced academic learning for many years and partly from negative aging and gender stereotypes—erroneous beliefs that traditional-age students are smarter or that men are more logical and therefore more academically capable (Compton, Cox, & Laanan, 2006). And for minority students, ethnic stereotypes about ability to learn and prejudicial treatment are also factors.

Role demands outside of school—from children, spouses, other family members, friends, and employers—pull many returning women in conflicting directions. Those reporting high stress typically are single parents with limited financial resources, or married women with high career aspirations, young children, and nonsupportive partners (Deutsch & Schmertz, 2011). When couples fail to rework divisions of household and child-care responsibilities to accommodate the woman's return to school, marital satisfaction declines (Sweet & Moen, 2007). As a classmate remarked to Anya, “I tried keeping the book open and

reading, cooking, and talking to the kids. It didn't work. So I had to say to Bill, ‘Can't you put in a load of laundry once in a while, get home earlier on just some nights?’ He forgets—I went through his going to graduate school!”

Because of multiple demands on their time, mature-age women, especially those with children still at home, tend to take fewer credits, experience more interruptions in their academic programs, and progress at a slower pace than mature-age men. Role overload is the most common reason for not completing their degrees (Bergman, Rose, & Shuck, 2015). But many express high motivation to work through those difficulties, referring to the excitement of learning, to the fulfillment academic success brings, and to their hope that a college education will improve both their work and family lives (Kinser & Deitchman, 2007).

### LOOK and LISTEN

Interview a nontraditional student on your campus about the personal challenges and rewards of working toward a degree at a later age.

### Supporting Returning Students

As these findings suggest, social supports for returning students can make the difference between continuing in school and dropping out. Adult students need family members and friends who encourage their efforts and enable them to find time for uninterrupted study. Anya's classmate explained, “My doubts subsided when one day, Bill volunteered, ‘You take your books and do what you need to do. I can cook dinner and do the laundry.’” Institutional services for returning students are

AP IMAGES/NANCY PALMIERI

This 50-year-old, a full-time undergraduate at Mount Holyoke College, is one of many nontraditional students in U.S. colleges and universities. Appropriate academic advising and encouragement from family members, friends, and faculty help middle-aged learners succeed.

## Applying what we Know

### Facilitating Adult Reentry to College

SOURCES OF SUPPORT	DESCRIPTION
Partner and children	Value and encourage educational efforts. Help with household tasks to permit time for uninterrupted study.
Extended family and friends	Value and encourage educational efforts.
Educational institution	Provide orientation programs and written information that inform adult students about services and social supports. Provide counseling and intervention addressing academic weaknesses, self-doubts about success, and matching courses to career goals. Facilitate peer networks through regular meetings, phone, and online contacts. Promote personal relationships with faculty. Encourage active engagement and discussion in classes and integration of course content with real-life experiences. Offer evening, Saturday, and off-campus classes and online courses. Provide financial aid for returning students, including those enrolled part-time. Initiate campaigns to recruit returning students, including those from low-income families and ethnic minority groups. Help students with young children find child-care arrangements and provide on-campus child care.
Workplace	Value and encourage educational efforts. Offer flexible work schedules to make possible coordination of job, educational, and family responsibilities.

also essential. Personal relationships with faculty, peer networks with other nontraditional students, evening and Saturday classes, online courses, and financial aid for returning students, including those enrolled part-time, increase the chances of academic success.

Although nontraditional students rarely require assistance in settling on career goals, they report a strong desire for help in choosing the most appropriate courses and for small, discussion-based classes that meet their learning and relationship needs. Academic advising and professional internship opportunities are vital, strongly affecting persistence (Bergman, Rose, & Shuck, 2015). Students from low-SES backgrounds often need special assistance, such as academic tutoring, sessions in confidence building and assertiveness, and—in the case of ethnic minorities—help adjusting to styles of learning that are at odds with their cultural background.

Applying What We Know above suggests ways to facilitate adult reentry to college. When support systems are in place, most returning students reap great personal benefits and do well academically. Succeeding at coordinating education, family, and work demands leads to gains in self-efficacy and admiration from family members, friends, and co-workers (Chao & Good, 2004). Nontraditional students especially value forming new relationships, sharing opinions and experiences, and relating subject matter to their own lives. Their greater ability to integrate knowledge results in an enhanced appreciation of classroom experiences and assignments (Knowles, Swanson, & Holton, 2011). And their presence in college classes provides valuable

intergenerational contact. As younger students observe the capacities and talents of older classmates, unfavorable stereotypes of aging decline.

After finishing her degree, Anya secured a position as a parish nurse with creative opportunities to counsel members of a large congregation about health concerns. Education granted her new life options, financial rewards, and higher self-esteem as she reevaluated her own competencies. Sometimes (though not in Anya's case) these revised values and increased self-reliance can spark other changes, such as a divorce or a new intimate partnership. In middle adulthood as in earlier years, education transforms development, often profoundly reshaping the life course.

### Ask yourself

**CONNECT** Most high-level government and corporate positions are held by middle-aged and older adults rather than by young adults. What cognitive capacities enable mature adults to perform these jobs well?

**APPLY** Marcella completed one year of college in her twenties. Now, at age 42, she has returned to earn a degree. Plan a set of experiences for Marcella's first semester that will increase her chances of success.

**REFLECT** What range of services does your institution offer to support nontraditional-age students? What additional supports would you recommend?

## Summary / chapter 15

### PHYSICAL DEVELOPMENT

#### Physical Changes (p. 508)

**15.1** Describe the physical changes of middle adulthood, paying special attention to vision, hearing, the skin, muscle–fat makeup, and the skeleton.

- The gradual physical changes begun in early adulthood continue in midlife, contributing to a revised physical self-image, with less emphasis on hoped-for gains and more on feared declines.
- Vision is affected by **presbyopia** (loss of the accommodative ability of the lens), reduced vision in dim light, increased sensitivity to glare, and diminished color discrimination. Risk of **glaucoma** increases.
- Age-related hearing loss, or **presbycusis**, begins with a decline in detection of high frequencies and then spreads to other tones. The ability to distinguish sounds occurring in close succession also recedes, and eventually, human speech becomes harder to decipher.

THOMAS BARWICK/STONE/GETTY IMAGES

- The skin wrinkles, loosens, and dries. Age spots develop, especially in women and in people exposed to the sun.
- Muscle mass declines and fat deposits increase, with notable sex differences in fat distribution. A low-fat diet and regular exercise, including resistance training, can offset both excess weight and muscle loss.
- Bone density declines, especially in women after menopause. Height loss and bone fractures can result.

**15.2** Describe reproductive changes in both sexes, along with associated physical and emotional symptoms, during middle adulthood.

- The **climacteric** in women, which occurs gradually as estrogen production drops and concludes with **menopause**, is often accompanied by physical and emotional symptoms, including hot flashes and depressive episodes. These reactions, however, vary widely with ethnicity and culture, SES, psychological stress, attitudes toward menopause, and other factors.
- **Hormone therapy** can reduce the discomforts of menopause, but its use increases the risk of cardiovascular disease, certain cancers, and cognitive declines.
- Although sperm production continues throughout life, quantity of semen diminishes, and more stimulation is required for an erection. Drugs are available to combat impotence, a condition that can undermine self-image.

#### Health and Fitness (p. 514)

**15.3** Discuss sexuality in middle adulthood and its association with relationship satisfaction.

- Frequency of sexual activity among heterosexual couples declines only modestly in middle adulthood. Intensity of sexual response also diminishes, yet most married people over age 50 say that sex is an important part of a healthy couple relationship.

**15.4** Discuss cancer, cardiovascular disease, and osteoporosis, noting risk factors and interventions.

- The death rate from cancer multiplies tenfold from early to middle adulthood. Heredity, biological aging, and environment all contribute to cancer. Today, 60 percent of affected individuals are cured. Regular screenings and various preventive steps can reduce the incidence of cancer and cancer deaths.
- Cardiovascular disease is a major cause of death in middle adulthood, especially among men. Symptoms include high blood pressure, high blood cholesterol, atherosclerosis, heart attack, arrhythmia, and angina pectoris. Quitting smoking, reducing blood cholesterol, exercising, and reducing stress can decrease risk and aid in treatment. Women experiencing a heart attack are often overlooked, misdiagnosed, or insufficiently treated.

- **Osteoporosis** affects 10 percent of people age 50 and older, primarily women. Adequate calcium and vitamin D, weight-bearing exercise, resistance training, and bone-strengthening medications can help prevent and treat osteoporosis.

© HERO IMAGES INC./ALAMY STOCK PHOTO

**15.5** Discuss the association of hostility and anger with heart disease and other health problems.

- Expressed hostility and a socially dominant interactive style, components of the **Type A behavior pattern**, predict heart disease and other health problems. Anger suppression is also related to health problems; a better alternative is to develop effective ways of handling stress and conflict.

#### Adapting to the Physical Challenges of Midlife (p. 520)

**15.6** Discuss the benefits of stress management, exercise, and hardiness in dealing effectively with the physical challenges of midlife.

- Effective stress management includes both problem-centered and emotion-centered coping, constructive approaches to anger reduction, and social support. In middle adulthood, people tend to cope with stress more effectively, often reporting lasting personal benefits.
- Regular exercise offers physical and psychological advantages, making it worthwhile for sedentary middle-aged people to begin exercising. Developing a sense of self-efficacy and having access to convenient, safe, and attractive exercise environments promote physical activity.
- **Hardiness** includes three personal qualities—control, commitment, and challenge—that motivate people to turn life's stressors into opportunities for resilience. A modest level of lifetime adversity seems to promote hardiness.

**15.7 Explain the double standard of aging.**

- Middle-aged women are more likely than their male counterparts to be viewed unfavorably, especially by men.

**COGNITIVE DEVELOPMENT****Changes in Mental Abilities** (p. 524)**15.8 Describe cohort effects on intelligence revealed by Schaie's Seattle Longitudinal Study.**

- Early cross-sectional research showed a peak in intelligence test performance at age 35 followed by a steep decline, whereas longitudinal evidence revealed modest gains in midlife. Using a sequential design, Schaie found that the cross-sectional, steep drop-off largely resulted from cohort effects, as each new generation experienced better health and education and more cognitively stimulating experiences.

**15.9 Describe changes in crystallized and fluid intelligence in middle adulthood, and discuss individual and group differences in intellectual development.**

- **Crystallized intelligence**, which depends on accumulated knowledge and experience, gains steadily through middle adulthood. In contrast, **fluid intelligence**, which depends more on basic information-processing skills, begins to decline in the twenties.
- In the Seattle Longitudinal Study, perceptual speed undergoes a steady, continuous decline. But other fluid skills, in addition to crystallized abilities, increase through middle adulthood, confirming that midlife is a time of peak performance on a variety of complex abilities.
- Midlifers' intellectual development is multidimensional, multidirectional, and plastic. Illness and unfavorable environments are linked to intellectual declines; stimulating occupations and leisure pursuits, flexible personalities, lasting marriages, good health, and economic advantage predict favorable cognitive development.

- In early and middle adulthood, women outperform men on verbal tasks and perceptual speed, whereas men excel at spatial skills. Gains in certain intellectual skills by baby boomers relative to the previous generation reflect advances in education, technology, environmental stimulation, and health care.

**Information Processing** (p. 527)**15.10 How does information processing change in midlife?**

- Speed of cognitive processing slows with age. According to one view, deteriorating neuronal connections, due to myelin breakdown, reduce reaction time. Another approach suggests that older adults experience greater loss of information as it moves through the cognitive system, resulting in slower processing.
- As processing speed slows, people perform less well on memory, reasoning, and problem-solving tasks, especially fluid-ability items. But other factors also predict age-related cognitive performances.
- Executive function declines with age: working memory diminishes, and inhibition and flexible shifting of attention become more challenging.

© JIM WEST/THE IMAGE WORKS

- Compared with younger individuals, older adults less often use memory strategies, resulting in decreased recall of studied information. But training, improved design of tasks, and metacognitive knowledge enable older adults to compensate for age-related decrements.

**15.11 Discuss the development of practical problem solving, expertise, and creativity in middle adulthood.**

- Middle-aged adults display continued growth in **practical problem solving**, largely due to gains in expertise. Creativity becomes more deliberately thoughtful and often shifts from generating unusual products to integrating ideas, and from concern with self-expression to more altruistic goals.

**Vocational Life and Cognitive Development** (p. 531)**15.12 Describe the relationship between vocational life and cognitive development.**

- Well into middle adulthood, stimulating, complex work augments flexible, abstract thinking. It also reduces the age-related decline in fluid abilities.

**Adult Learners: Becoming a Student in Midlife** (p. 532)**15.13 Discuss the challenges that adults face in returning to college, ways to support returning students, and benefits of earning a degree in midlife.**

- Adults returning to college and graduate school are more often women. Returning students must cope with a lack of recent practice at academic work; negative stereotypes of aging, gender, and ethnicity; and demands of multiple roles.
- Social support from family and friends and institutional services can help returning students succeed. Further education results in enhanced competencies, new relationships, intergenerational contact, and reshaped life paths.

## Emotional and Social Development in Middle Adulthood

Midlife is a time of increased generativity—giving to and guiding younger generations. At a nonprofit bike store in an economically disadvantaged neighborhood, a volunteer derives a deep sense of satisfaction from providing youths with free bikes, and teaching them how to care for them.

One weekend when Devin, Trisha, and their 24-year-old son, Mark, were vacationing together, the two middle-aged parents knocked on Mark's hotel room door. "Your dad and I are off to see a crafts exhibit," Trisha explained. "Feel free to stay behind," she offered, recalling Mark's dislike for such events as an adolescent. "We'll be back around noon for lunch."

"That exhibit sounds great!" Mark replied. "I'll meet you in the lobby."

"Sometimes I forget he's an adult!" exclaimed Trisha as she and Devin returned to their room to grab their coats. "It's been great to have Mark with us—like spending time with a good friend."

In their forties and fifties, Trisha and Devin built on earlier strengths and intensified their commitment to leave a legacy for others. When Mark faced a difficult job market after graduating from college, he returned home to live with Trisha and Devin and remained there for several years.

With their support, he took graduate courses while working part-time, found steady employment in his late twenties, fell in love, and married in his mid-thirties. With each milestone, Trisha and Devin felt a sense of pride at having escorted a member of the next generation into responsible adult roles. Family activities, which had declined during Mark's adolescent and college years, increased as Trisha and Devin related to their son as an enjoyable adult companion. Challenging careers and more time for community involvement, leisure pursuits, and each other contributed to a richly diverse and gratifying time of life.

The midlife years were not as smooth for two of Trisha and Devin's friends. Approaching age 50 and fearing that she might grow old alone, Jewel frantically pursued her quest for an intimate partner. She attended singles events, used online dating services, and traveled in hopes of meeting a like-minded companion. Jewel also had compensating satisfactions—friendships that had grown more meaningful, a warm relationship with a nephew and niece, and a successful consulting business.

Tim, Devin's best friend from graduate school, had been divorced for over five years. Recently, he had met Elena and had come to love her deeply. But Elena was in the midst of major life changes. In addition to her own divorce, she was dealing with a troubled daughter and a career change. Whereas Tim had reached the peak of his career and was ready to enjoy life, Elena wanted to recapture much of what she had missed in earlier decades, including opportunities to realize her talents. "I don't know where I fit into Elena's plans," Tim wondered aloud on the phone with Trisha.

With the arrival of middle adulthood, half or more of the lifespan is over. Increasing awareness of limited time ahead prompts adults to reevaluate the meaning of their lives, refine and strengthen their identities, and reach out to future generations. Most middle-aged people make modest adjustments in their outlook, goals, and daily lives.

HOLA IMAGES/GETTY IMAGES

But some experience profound inner turbulence and initiate major changes, often in an effort to make up for lost time. Together with advancing years, family and work transitions contribute greatly to emotional and social development.

More midlifers are addressing these tasks than ever before, now that the majority of baby boomers are in their fifties and sixties (see page 12 in Chapter 1 to review how baby boomers have reshaped the life course). And the current midlife generation is healthier, better educated, and—despite the late-2000s economic recession—more financially secure than any previous midlife cohort (Mitchell, 2016). As our discussion will reveal, they have brought increased self-confidence, social consciousness, and vitality—along with great developmental diversity—to this period of the lifespan.

A monumental survey called *Midlife Development in the United States (MIDUS)*, conducted in the mid-1990s, has contributed enormously to our understanding of midlife emotional and social development. Conceived by a team of researchers spanning diverse fields, including psychology, sociology, anthropology, and medicine, the aim of MIDUS was to generate new knowledge on the challenges faced by middle-aged adults. Its nationally representative sample included over 7,000 U.S. 25- to 75-year-olds, enabling those in the middle years to be compared with younger and older individuals. Through telephone interviews and self-administered questionnaires, participants responded to over 1,100 items addressing wide-ranging psychological, health, and background factors, yielding unprecedented breadth of information in a single study. The research endeavor also included “satellite” studies, in which subsamples of respondents were questioned in greater depth on key topics. And it was extended longitudinally, with 75 percent of the sample recontacted in the early to mid-2000s. In the early 2010s, researchers expanded the MIDUS sample to include over 3,500 additional U.S. participants (Delaney, 2014). Around the same time, they launched a Japanese offshoot, called Midlife in Japan (MIDJA), consisting of over 1,000 participants.

MIDUS has greatly enriched our knowledge of the *multi-dimensional* and *multidirectional* nature of midlife change, and it promises to be a rich source of information about middle adulthood and beyond for many years to come. Hence, our discussion repeatedly draws on MIDUS, at times delving into its findings, at other times citing them alongside those of other investigations. Let’s turn now to Erikson’s theory and related research, to which MIDUS has contributed. ●

## Erikson’s Theory: Generativity versus Stagnation

### 16.1 According to Erikson, how does personality change in middle age?

Erikson’s psychological conflict of midlife is called **generativity versus stagnation**. Generativity involves reaching out to others in ways that give to and guide the next generation. Recall from Chapter 14 that generativity is under way in early adulthood through work, community service, and childbearing and child rearing. Generativity expands greatly in midlife, when adults focus more intently on extending commitments beyond oneself (identity) and one’s life partner (intimacy) to a larger group—family, community, or society. The generative adult combines the need for self-expression with the need for communion, integrating personal goals with the welfare of the larger social world (McAdams, 2014). The resulting strength is the capacity to care for others in a broader way than previously.

Erikson (1950) selected the term *generativity* to encompass everything generated that can outlive the self and ensure society’s continuity and improvement: children, ideas, products, works of art. Although parenting is a major means of realizing generativity,

JEAN-MARC GIBOUX/GETTY IMAGES

Through his work with severely malnourished children in Niger, this nurse, affiliated with the Nobel Prize–winning organization Doctors Without Borders, integrates personal goals with a broader concern for society. ●

it is not the only means: Adults can be generative in other family relationships (as Jewel was with her nephew and niece), as mentors in the workplace, in volunteer endeavors, and through many forms of productivity and creativity.

Notice, from what we have said so far, that generativity brings together personal desires and cultural demands. On the personal side, middle-aged adults feel a need to be needed—to attain symbolic immortality by making a contribution that will survive their death (Kotre, 1999; McAdams, Hart, & Maruna, 1998). This desire may stem from a deep-seated evolutionary urge to protect and advance the next generation. On the cultural side, society imposes a social clock for generativity in midlife, requiring adults to take responsibility for the next generation through their roles as parents, teachers, mentors, leaders, and coordinators (McAdams & Logan, 2004). And according to Erikson, a culture’s “belief in the species”—the conviction that life is good and worthwhile, even in the face of human destructiveness and deprivation—is a major motivator of generative action. Without this optimistic worldview, people would have no hope of improving humanity.

The negative outcome of this stage is stagnation: Once people attain certain life goals, such as marriage, children, and career success, they may become self-centered and self-indulgent. Adults with a sense of stagnation express their self-absorption in many ways—through lack of interest in young people (including their own children), through a focus on what they can get from others rather than what they can give, and through taking little interest in being productive at work, developing their talents, or bettering the world in other ways.

Some researchers study generativity by asking people to rate themselves on generative characteristics, such as feelings of duty to help others in need or obligation to be an involved citizen. Others ask open-ended questions about life goals, major high points, and most satisfying activities, rating people’s responses for generative references. And still others look for generative themes in people’s narrative descriptions of themselves (Keyes & Ryff, 1998a, 1998b; McAdams, 2011, 2014; Newton & Stewart, 2010; Rossi, 2001, 2004b). Whichever method is used, generativity tends to increase in midlife among people diverse in SES and ethnicity. And as the Social Issues: Health box on page 540 illustrates, generativity is a major unifying theme in middle-aged adults’ life stories.

Just as Erikson’s theory suggests, highly generative people appear especially well-adjusted—low in anxiety and depression; high in autonomy, self-acceptance, and life satisfaction; more open to different viewpoints; and more likely to have successful marriages and close friends (An & Cooney, 2006; Grossbaum & Bates, 2002; Versey & Newton, 2013; Westermeyer, 2004). They also demonstrate workplace leadership qualities aimed at enhancing the success of younger colleagues, and they care greatly about the welfare of others in general (Peterson, 2002; Zacher et al., 2011). For example, generativity is associated with more effective child rearing—higher valuing of trust, open communication, transmission of generative values to children, and an authoritative style (Peterson, 2006; Peterson & Duncan, 2007;

**FIGURE 16.1** Relationship of middle-aged adults’ generativity to civic, political, and religious engagement. Among a sample of European-American and African-American 55- to 59-year-olds, self-rated generativity was positively correlated with diverse measures of involvement in community and society—especially, public service motivation (attraction to public policy making, commitment to public interest causes) and civic engagement (participating in community organizations, raising money for charity), but also political participation (voting, expressing political opinions to others) and participation in a religious community. (Based on Jones & McAdams, 2013.)

Pratt et al., 2008). And as Figure 16.1 illustrates, midlife generativity is positively correlated with broad engagement in community and society (Jones & McAdams, 2013).

Although these findings characterize adults of all backgrounds, individual differences in contexts for generativity exist. Having children seems to foster generative development in both men and women. In some studies, including the MIDUS survey, fathers scored higher in generativity than childless men (Marks, Bumpass, & Jun, 2004; McAdams & de St. Aubin, 1992). Similarly, in an investigation of well-educated women from ages 43 to 63, those with family commitments (with or without a career) expressed greater generative concerns than childless women who were solely focused on their careers (Newton & Stewart, 2010). Perhaps parenting spurs especially tender, caring attitudes toward succeeding generations.

For low-SES men with troubled pasts as sons, students, workers, and intimate partners, fatherhood can provide a context for highly generative, positive life change (Roy & Lucas, 2006). At times, these fathers express this generativity as a refusal to pass on their own history of suffering. As one former gang member, who earned an associate’s degree and struggled to keep his teenage sons off the streets, explained, “I came through the depths of hell to try to be a father. I let my sons know, ‘You’re never without a daddy, don’t you let anybody tell you that.’ I tell them that if me and your mother separate, I make sure that wherever I go, I build something for you to come to” (p. 153).

## Social Issues: Health

### Generative Adults Tell Their Life Stories

To clarify how highly generative adults make sense of their lives, researchers interviewed two groups of midlifers: those who often behave generatively and those who seldom do. Participants were asked to relate their life stories, including a high point, a low point, a turning point, and important scenes from childhood, adolescence, and adulthood (McAdams, 2011, 2013b). Story lines and themes revealed that adults high and low in generativity reconstruct their past and anticipate their future in strikingly different ways.

Narratives of highly generative people usually contained an orderly sequence of events that the researchers called a commitment story, in which adults give to others as a means of giving back to family, community, and society. The generative storyteller typically describes an early special advantage (such as a supportive family or a talent), along with early awareness of the suffering of others. This clash between blessing and suffering motivates the person to view the self as “called,” or morally committed, to being good to others. In commitment stories, the theme of redemption is prominent. Highly generative adults frequently describe scenes in which extremely negative life events, involving frustration, failure, loss, or death, are redeemed, or made better, by good outcomes—personal renewal, improvement, and enlightenment.

Consider a story related by Diana, a 49-year-old fourth-grade teacher. Born in a small town to a minister and his wife, Diana was a favorite among the parishioners, who showered her with attention and love. When she was 8, however, her life hit its lowest point: As she looked on in horror, her younger brother ran into the street and was hit by a car; he died later that day. Afterward, Diana, sensing her father’s anguish, tried—unsuccessfully—to be the “son” he had lost. But the scene ends on an upbeat note, with

Diana marrying a man who forged a warm bond with her father and who became accepted “as his own son.” One of Diana’s life goals was to improve her teaching, because “I’d like to give something back . . . to grow and help others grow” (McAdams et al., 1997, p. 689). Her interview overflowed with expressions of generative commitment.

Whereas highly generative adults tell stories in which bad scenes turn good, less generative adults relate stories with themes of contamination, in which good scenes turn bad. For example, a good first year of college turns sour when a professor grades unfairly. A young woman loses weight and looks good but can’t overcome her low self-esteem.

Why are life-story redemption events linked to generativity? First, some adults may view their generative activities as a way to redeem negative aspects of their lives. In a study of the life stories of ex-convicts who turned away from crime, many spoke of a strong desire to do good works as penance for their transgressions (Maruna, LeBel, & Lanier, 2004). Second, generativity seems to entail the conviction that the imperfections of today can be transformed into a better tomorrow. Through guiding and giving to the next generation, mature adults increase the chances that the mistakes of the past will not happen again. Finally, interpreting one’s own life in terms of redemption may help sustain the perseverance needed to overcome the difficult challenges that generative

Former heroin addict Harry Olsen spent eight years in and out of prison for drug convictions and other crimes. When he was released at age 39, he was overwhelmed by the prospect of reentering society but determined to transform himself. In search of direction and purpose, Olsen founded a nonprofit organization dedicated to helping other ex-convicts transition to life outside prison.

activities—from rearing children to advancing societies—usually present.

Life stories offer insight into how people imbue their lives with meaning and purpose. Although adults high and low in generativity do not differ in the number of positive and negative events included in their narratives, they interpret those events differently. Commitment stories, filled with redemption, involve a way of thinking about the self that fosters a caring, compassionate approach to others (McAdams & Logan, 2004). Such stories help people realize that although their own personal story will someday end, other stories will follow, due in part to their own generative efforts.

The more redemptive events adults include in their life stories, the higher their self-esteem, life satisfaction, and certainty that the challenges of life are meaningful, manageable, and rewarding (Lilgendahl & McAdams, 2011; McAdams & Guo, 2015). Researchers still have much to learn about factors that lead people to view good as emerging from adversity.

Finally, compared with European Americans, African Americans more often engage in certain types of generativity. They express a stronger desire to leave a legacy to their broader community (rather than just their immediate family) and, consistent with that goal, offer more social support to community members (Hart et al., 2001; Newton & Jones, 2016). A life history of greater support from church and extended family may strengthen these generative values and actions. Among European Americans, religiosity and spirituality are also positively associated with generative activity (Son & Wilson, 2011; Wink & Dillon, 2008). Highly generative middle-aged adults often indicate that as children and adolescents, they internalized moral values rooted in a religious tradition and sustained their commitment to those values, which provided lifelong encouragement for generative action (McAdams, 2013a). Especially in individualistic societies, belonging to a religious community or believing in a higher being may help preserve generative commitments.

## Other Theories of Psychosocial Development in Midlife

**16.2** Describe Levinson's and Vaillant's views of psychosocial development in middle adulthood, and discuss similarities and differences between men and women.

**16.3** Does the term *midlife crisis* reflect the typical experience of middle adulthood, and is midlife accurately characterized as a stage?

Erikson's broad sketch of psychosocial change in midlife has been extended by Levinson and Vaillant. Let's revisit their theories, which were introduced in Chapter 14.

### Levinson's Seasons of Life

Return to page 447 to review Levinson's eras (seasons of life). His interviews revealed that with the transition to middle age, adults become more aware that from now on, more time will lie behind than ahead, so they view the remaining years as increasingly precious. This leads some to make drastic revisions in their life structure: divorcing, remarrying, changing careers, or displaying enhanced creativity. Others make smaller changes in the context of marital and occupational stability.

Whether these years bring a gust of wind or a storm, most people turn inward for a time, focusing on personally meaningful living. According to Levinson, to reassess and rebuild their life structure, middle-aged adults must confront four developmental tasks. Each requires the individual to reconcile two opposing tendencies within the self, attaining greater internal harmony.

- *Young-old*: The middle-aged person must seek new ways of being both young and old. This means giving up certain youthful qualities, transforming others, and finding positive meaning in being older. Perhaps because of the double standard of aging (see pages 523–524 in Chapter 15), most

middle-aged women express concern about appearing less attractive as they grow older (Rossi, 2004a). But middle-aged men—particularly non-college-educated men, who often hold blue-collar jobs requiring physical strength and stamina—are also highly sensitive to physical aging (Miner-Rubino, Winter, & Stewart, 2004).

Compared with previous midlife cohorts, U.S. baby boomers are especially interested in controlling physical changes—a desire that has helped energize a huge industry of anti-aging cosmetic products and medical treatments (Jones, Whitbourne, & Skultety, 2006). And sustaining a youthful *subjective age* (feeling younger than one's actual age) is positively related to self-esteem and psychological well-being, with stronger associations among American than Western-European middle-aged and older adults (Keyes & Westerhof, 2012; Westerhof & Barrett, 2005; Westerhof, Whitbourne, & Freeman, 2012). In the more individualistic U.S. context, a youthful self-image seems more important for viewing oneself as self-reliant and capable of planning for an active, fulfilling late adulthood.

- *Destruction–creation*: With greater awareness of mortality, the middle-aged person focuses on ways he or she has acted destructively. Past hurtful acts toward parents, intimate partners, children, friends, and co-workers are countered by an intensified desire to be generative, through charitable giving, community volunteering, mentoring young people, or fashioning creative products.
- *Masculinity–femininity*: The middle-aged person must better balance masculine and feminine parts of the self. For men, this means greater acceptance of “feminine” traits of nurturance and caring, which enhance close relationships and compassionate exercise of authority in the workplace. For women, it generally means greater openness to “masculine” characteristics of autonomy and assertiveness. Recall from Chapter 8 that people who combine masculine and feminine traits have an androgynous gender identity. Later we will see that androgyny is associated with favorable personality traits and adjustment.
- *Engagement–separateness*: The middle-aged person must forge a better balance between engagement with the external world and separateness. For many men, and for women with successful careers, this may mean reducing concern with achievement in favor of attending more fully to oneself. But some women who have been devoted to child rearing or an unfulfilling job may feel compelled to move in the other direction, pursuing a long-desired ambition (Etaugh, 2013). At age 48, Elena left her position as a reporter for a small-town newspaper, earned an advanced degree in creative writing, accepted a college teaching position, and began writing a novel. Tim, in contrast, recognized his intense desire for a gratifying romantic partnership. By scaling back his own career, he realized he could grant Elena the time and space she needed to rebuild her work life—and that doing so might deepen their attachment to each other.

AP PHOTO/JULIE JACOBSON

Individuals in blue-collar jobs with few possibilities for advancement may seek alternative ways to make their work more meaningful. This construction worker became a union shop steward, representing the interests of her coworkers in dealings with management.

People who flexibly modify their identities in response to age-related changes yet maintain a sense of self-continuity are more aware of their own thoughts and feelings and are higher in self-esteem and life satisfaction (Sneed et al., 2012). But adjusting one's life structure to incorporate the effects of aging requires supportive social contexts. When poverty, unemployment, and lack of a respected place in society dominate the life course, energies are directed toward survival rather than realistically addressing age-related changes. And even adults whose jobs are secure and who live in economically advantaged neighborhoods may find that employment conditions restrict possibilities for growth by placing too much emphasis on productivity and profit and too little on the meaning of work. In her early forties, Trisha left a large law firm, where she felt constant pressure to bring in high-fee clients and received little acknowledgment of her efforts, for a small practice.

Opportunities for advancement ease the transition to middle adulthood. Yet these are less available to women than to men. Individuals of both sexes in blue-collar jobs also have few possibilities for promotion. Consequently, they make whatever vocational adjustments they can—becoming active union members, shop stewards, or mentors of younger workers (Christensen & Larsen, 2008). Many men find compensating rewards in moving to the senior generation of their families.

## Vaillant's Adaptation to Life

Whereas Levinson interviewed 35- to 45-year-olds, Vaillant (1977, 2002)—in his longitudinal research on well-educated men and women—followed participants past the half-century mark. Recall from Chapter 14 how adults in their late fifties and sixties extend their generativity, becoming “keepers of meaning,” or guardians of their culture (see page 477). Vaillant reported that the most-successful and best-adjusted entered a calmer, quieter time of life. “Passing the torch”—concern that the positive aspects of their culture survive—became a major preoccupation.

In societies around the world, older people are guardians of traditions, laws, and cultural values. This stabilizing force holds in check too-rapid change sparked by the questioning and challenging of adolescents and young adults. As people approach the end of middle age, they focus on longer-term, less-personal goals, such as the state of human relations in their society. And they become more philosophical, accepting the fact that not all problems can be solved in their lifetime.

## Is There a Midlife Crisis?

Levinson (1978, 1996) reported that most men and women in his samples experienced substantial inner turmoil during the transition to middle adulthood. Yet Vaillant (1977, 2002) saw few examples of crisis but, rather, slow and steady change. These contrasting findings raise the question of how much personal upheaval actually accompanies entry to midlife. Are self-doubt and stress especially great during the forties, and do they prompt major restructuring of the personality, as the term **midlife crisis** implies?

Trisha and Devin moved easily into this period, whereas Jewel, Tim, and Elena engaged in considerable questioning of their situations and sought alternative life paths. Clearly, wide individual differences exist in response to midlife. Yet Americans often assume that a midlife crisis will occur between ages 40 and 50, perhaps because of culturally induced apprehension of aging. But little evidence supports this view of middle age as a turbulent time.

When MIDUS participants were asked to describe “turning points” (major changes in the way they felt about an important aspect of their lives) that had occurred during the past five years, most were positive, involving fulfilling a dream or learning something good about oneself (Wethington, Kessler, & Pixley, 2004). Overall, turning points rarely resembled midlife crises. Even negative turning points generally led to personal growth—for example, a layoff that sparked a positive career change or a shift in energy from career to personal life.

Asked directly if they had ever experienced something they would consider a midlife crisis, only one-fourth of the MIDUS respondents said yes. And they defined such events more loosely than researchers do. Some reported a crisis well before age 40, others well after age 50. And most attributed it not to age but rather to challenging life events (Wethington, 2000). For example, Elena had considered both a divorce and a new career long before she initiated these changes. In her thirties, she separated from her husband; later she reconciled with him and told him that she desired to return to school, which he firmly opposed. She put her own life on hold because of her daughter's academic and emotional difficulties and her husband's resistance.

Another way of exploring midlife questioning is to ask adults about life regrets—attractive opportunities for life-changing activities they did not pursue or lifestyle changes they did not make. Among a nationally representative sample of Americans, life regrets centered mainly on romantic and family relationships, followed by education, career, finances, parenting, and health (see Figure 16.2) (Morrison & Roese, 2011). Experiencing

**FIGURE 16.2** Life regrets most often mentioned by a nationally representative sample of Americans. Researchers telephoned 370 U.S. adults diverse in SES and ethnicity and asked each to describe one life salient regret. (Based on Morrison & Roese, 2011.)

regrets is consistently associated with less favorable psychological well-being (Schiebe & Epstude, 2016). But regrets can also serve a positive function if people mull over what went wrong in the past and, based on new insights, take whatever corrective action is possible.

By late midlife, with less time ahead to make life changes, people's interpretation of regrets plays a major role in their well-being. Mature, contented adults acknowledge a past characterized by some lost opportunities, have thought deeply about them, and feel stronger because of them. At the same time, they are able to disengage from them, investing in currently attainable, personally rewarding goals (King & Hicks, 2007). Among a sample of several hundred 60- to 65-year-olds diverse in SES, about half expressed at least one regret. Compared to those who had not resolved their disappointments, those who had come to terms with them (accepted and identified some eventual benefits) or had "put the best face on things" (identified benefits but still had some lingering regret) reported better physical health and greater life satisfaction (Torges, Stewart, & Miner-Rubino, 2005).

In sum, life evaluation is common during middle age. Most people make changes that are best described as turning points rather than drastic alterations of their lives. By midlife, an increasing number find that aspects of their life paths can no longer be modified, but they often come to see the "silver lining" in their circumstances (King & Hicks, 2007; Morrison & Roese, 2011). The few midlifers who are in crisis typically have had early adulthoods in which gender roles, family pressures, or low income and poverty severely limited their ability to realize personal goals, at home or in the wider world.

## Stage or Life Events Approach

That crisis and major restructuring in midlife are rare raises, once again, a question we considered in Chapter 14: Can adult

psychosocial changes be organized into stages, as Erikson's, Levinson's, and Vaillant's theories indicate? A growing number of researchers believe the mid-adult transition is not stagelike (Freund & Ritter, 2009; McAdams, 2014; Srivastava et al., 2003). Some regard it as simply an adaptation to normative life events, such as children growing up, reaching the crest of a career, and impending retirement.

Yet recall from earlier chapters that life events are no longer as age-graded as they were in the past. Their timing is so variable that they cannot be the sole cause of midlife change. Today, most experts view adaptation during midlife as the combined result of growing older and social experiences (Lachman, 2004; Sneed, Whitbourne, & Culang, 2006). Return to our discussion of the rise in generativity in middle adulthood on pages 538–539, and notice how both factors are involved.

Finally, in describing their lives, the large majority of middle-aged people report troubling times that prompt new understandings and goals. As we look closely at emotional and social development in middle adulthood, we will see that this period, like others, is characterized by both continuity and change. With this in mind, let's turn to the diverse inner concerns and outer experiences that contribute to psychological well-being and decision making in midlife.

## Ask yourself

**CONNECT** Describe evidence on life regrets illustrating that adaptation to midlife is the combined result of growing older and social experiences.

**APPLY** After years of experiencing little personal growth at work, 42-year-old Mel looked for a new job and received an attractive offer in another city. Although he felt torn between leaving close friends and pursuing a long-awaited career opportunity, after several weeks of soul searching, he took the new job. Was Mel's dilemma a midlife crisis? Why or why not?

**REFLECT** Think of a middle-aged adult whom you admire. Describe the various ways that individual expresses generativity.

## Stability and Change in Self-Concept and Personality

**16.4** Describe changes in self-concept, personality, and gender identity in middle adulthood.

**16.5** Discuss stability and change in the "big five" personality traits in adulthood.

Midlife changes in self-concept and personality reflect growing awareness of a finite lifespan, longer life experience, and generative concerns. Yet certain aspects of personality remain stable, revealing the persistence of individual differences established during earlier periods.

## Possible Selves

On a business trip, Jewel found a spare afternoon to visit Trisha. Sitting in a coffee shop, the two women reminisced about the past and thought aloud about the future. “It’s been tough living on my own and building the business,” Jewel said. “What I hope for is to become better at my work, to be more community-oriented, and to stay healthy and available to my friends. Of course, I would rather not grow old alone, but if I don’t find that special person, I suppose I can take comfort in the fact that I’ll never have to face divorce or widowhood.”

Jewel is discussing **possible selves**, future-oriented representations of what one hopes to become and what one is afraid of becoming. Possible selves are the temporal dimension of self-concept—what the individual is striving for and attempting to avoid. To lifespan researchers, these hopes and fears are just as vital in explaining behavior as people’s views of their current characteristics. Indeed, possible selves may be an especially strong motivator of action in midlife, as adults attach increased meaning to time (Frazier & Hooker, 2006). As we age, we may rely less on social comparisons in judging our self-worth and more on temporal comparisons—how well we are doing in relation to what we had planned.

Throughout adulthood, the personality traits people assign to their current selves show considerable stability. A 30-year-old who says he is cooperative, competent, outgoing, or successful is likely to report a similar picture at a later age. But reports of possible selves change greatly. Adults in their early twenties mention many possible selves, and their visions are lofty and idealistic—being “perfectly happy,” “rich and famous,” “healthy throughout life,” and not being “down and out” or “a person who does nothing important.” With age, possible selves become fewer in number, more modest and concrete, and less far-off in realization. Most middle-aged people no longer desire to be the best or the most successful in life. Instead, they are largely concerned with performance of roles and responsibilities already begun—“being competent at work,” “being a good husband and father,” “putting my children through college,” “staying healthy,” and not being “a burden to my family” or “without enough money to meet my daily needs” (Bybee & Wells, 2003; Chessell et al., 2014; Cross & Markus, 1991).

What explains these shifts in possible selves? Because the future no longer holds limitless opportunities, adults preserve mental health by adjusting their hopes and fears. To stay motivated, they must maintain a sense of unachieved possibility, yet they must still manage to feel good about themselves and their lives despite disappointments (Lachman & Bertrand, 2002). For example, Jewel no longer desired to be an executive in a large company, as she had in her twenties. Instead, she wanted to grow in her current occupation. And although she feared loneliness in old age, she reminded herself that marriage can lead to equally negative outcomes, such as divorce and widowhood—possibilities that made not having attained an important interpersonal goal easier to bear.

Unlike current self-concept, which is constantly responsive to others’ feedback, possible selves (though influenced by others) can be defined and redefined by the individual, as needed. Consequently, they permit affirmation of the self, even when things are not going well in the present (Bolkan & Hooker, 2012). In a study of middle-aged and older adults, those with *balanced possible selves*—related hoped-for and feared outcomes, such as “a better relationship with my grown sons” and “not alienating my daughters-in-law”—made greater self-rated progress toward attaining their self-relevant goals over a 100-day period (Ko, Mejía, & Hooker, 2014). Because balanced possible selves provide both an approach and avoidance focus, they may be more motivating than either hoped-for or feared possible selves alone.

Researchers believe that possible selves may be the key to continued well-being in adulthood, as people revise these future images to achieve a better match between desired and attainable goals. Many studies reveal that the self-esteem of middle-aged and older individuals equals or surpasses that of younger people (Robins & Trzesniewski, 2005). A major reason may be the protective effect of possible selves.

## Self-Acceptance, Autonomy, and Environmental Mastery

An evolving mix of competencies and experiences leads to changes in certain aspects of personality during middle adulthood. In Chapter 15, we noted that midlife brings gains in expertise and practical problem solving. Middle-aged adults also offer more complex, integrated descriptions of themselves than do younger and older individuals (Labouvie-Vief, 2003, 2015). Furthermore, midlife is typically a period in which the number of social roles peaks—spouse, parent, worker, and engaged community member. And status at work and in the community typically rises, as adults take advantage of opportunities for leadership and other complex responsibilities.

These changes in cognition and breadth of roles undoubtedly contribute to other gains in personal functioning. In research on adults ranging in age from the late teens into the seventies, and in cultures as distinct as the United States and Japan, three qualities increased from early to middle adulthood:

- *Self-acceptance*: More than young adults, middle-aged people acknowledged and accepted both their good and bad qualities and felt positively about themselves and life.
- *Autonomy*: Middle-aged adults saw themselves as less concerned about others’ expectations and evaluations and more concerned with following self-chosen standards.
- *Environmental mastery*: Middle-aged people saw themselves as capable of managing a complex array of tasks easily and effectively (Karasawa et al., 2011; Ryff & Keyes, 1995).

As these findings indicate, midlife is generally a time of increased comfort with the self, independence, assertiveness, and commitment to personal values (Helson, Jones, & Kwan, 2002; Keyes,

Shmotkin, & Ryff, 2002; Stone et al., 2010). Many midlifers seem to conclude that through effort and self-discipline, they have come close to fulfilling their potential—a likely reason for the rise in overall life satisfaction from early to middle adulthood in longitudinal research (Galambos et al., 2015). Increased contentment with oneself and one's life accomplishments might explain why middle age is sometimes referred to as “the prime of life.”

At the same time, factors contributing to psychological well-being differ substantially among cohorts, as self-reports gathered from 25- to 65-year-old MIDUS survey respondents reveal (Carr, 2004). Among women who were born during the baby-boom years or later, and who thus benefited from the women's movement, balancing career with family predicted greater self-acceptance and environmental mastery. But also consider that women born before or during World War II who sacrificed career to focus on child rearing—expected of young mothers in the 1950s and 1960s—were similarly advantaged in self-acceptance. Likewise, men who were in step with prevailing social expectations scored higher in well-being. Baby-boom and younger men who modified their work schedules to make room for family responsibilities—who fit their cohort's image of the “good father”—were more self-accepting. But older men who made this accommodation scored much lower in self-acceptance than those who focused on work and conformed to the “good provider” ideal of their times. (See the Biology and Environment box on pages 546–547 for additional influences on midlife psychological well-being.)

Notions of well-being, however, vary among cultures. In comparisons of Japanese and Korean adults with same-age U.S. MIDUS participants, the Japanese and Koreans reported lower levels of psychological well-being, largely because they were less willing than the Americans to endorse individualistic traits, such as self-acceptance and autonomy, as characteristic of themselves (Karasawa et al., 2011; Keyes & Ryff, 1998b). Consistent with their interdependent orientation, Japanese and Koreans' highest well-being scores were on positive relations with others. The Korean participants clarified that they viewed personal fulfillment as achieved through family, especially the success of children. Americans also regarded family relations as relevant to well-being but placed greater emphasis on their own traits and accomplishments than on their children's.

## Coping with Daily Stressors

In Chapter 15, we discussed the importance of stress management in preventing illness. It is also vital for psychological well-being. In a MIDUS satellite study in which more than 1,000 participants were interviewed on eight consecutive evenings, researchers found an early- to mid-adulthood plateau in frequency of daily stressors, followed by a decline as work and family responsibilities ease and leisure time increases (see Figure 16.3) (Almeida & Horn, 2004). Women reported more frequent role overload (conflict among roles of employee, spouse, parent, and caregiver of an aging parent) and family-network and child-

**FIGURE 16.3** Age-related changes in daily stressors among men and women. In a MIDUS satellite study, researchers interviewed more than 1,000 adults on eight consecutive evenings. Findings revealed an early- to mid-adulthood plateau, followed by a decline as work and family responsibilities ease and leisure time increases. (From D. M. Almeida & M. C. Horn, 2004, “Is Daily Life More Stressful During Middle Adulthood?” in O. G. Brim, C. D. Ruff, and R. C. Kessler [Eds.], *How Healthy Are We? A National Study of Well-Being at Midlife*. Chicago: The University of Chicago Press, p. 438. Adapted by permission of The University of Chicago Press.)

related stressors, men more work-related stressors, but both genders experienced all varieties. Compared with older people, young and midlife adults also perceived their stressors as more disruptive and unpleasant, perhaps because they often experienced several at once, and many involved financial risks and children.

But recall, also, from Chapter 15 that midlife brings an increase in effective coping strategies. Middle-aged individuals are more likely to identify the positive side of difficult situations, postpone action to permit evaluation of alternatives, anticipate and plan ways to handle future discomforts, and use humor to express ideas and feelings without offending others (Diehl, Coyle, & Labouvie-Vief, 1996; Proulx & Aldwin, 2016). Notice how these efforts flexibly draw on both problem-centered and emotion-centered strategies.

Why might effective coping increase in middle adulthood? Other personality changes seem to support it. Complex, integrated, coherent self-descriptions—which increase in midlife, indicating an improved ability to blend strengths and weaknesses into an organized picture—predict a stronger sense of personal control over outcomes and good coping strategies (Hay & Diehl, 2010; Labouvie-Vief, 2015). Midlife gains in emotional stability and confidence in handling life's problems may also contribute (Roberts et al., 2007; Roberts & Mroczek, 2008). These attributes predict work and relationship effectiveness—outcomes that reflect the sophisticated, flexible coping of middle age.

Some midlifers, however, experience stressors so intense that their capacity to cope disintegrates. Over the past 15 years,

## Biology and Environment

### What Factors Promote Psychological Well-Being in Midlife?

For Trisha and Devin, midlife brought contentment and high life satisfaction. But the road to happiness was rockier for Jewel, Tim, and Elena. What factors contribute to individual differences in psychological well-being at midlife? Consistent with the lifespan perspective, biological, psychological, and social forces are involved, and their effects are interwoven.

#### Good Health and Exercise

Good health affects energy and zest for life at any age. But during middle and late adulthood, taking steps to improve health and prevent disability becomes a better predictor of psychological well-being. Many studies confirm that engaging in regular exercise—walking, dancing, jogging, or swimming—is more strongly associated with self-rated health and a positive outlook in older than in younger adults (Bherer, 2012). Middle-aged people who maintain an exercise regimen are likely to perceive themselves as particularly active for their age and, therefore, to feel a special sense of accomplishment (Netz et al., 2005). In addition, physical activity enhances self-efficacy and effective stress management (see page 521 in Chapter 15). And sustained, moderate intensity physical activity is linked to

better executive function, more so in middle age than early adulthood (Maxwell & Lynn, 2015; Weinstein, Lydick, & Biswabharati, 2014). Improved executive function, in turn, may contribute to midlifers' self-efficacy and self-regulation.

#### Sense of Control and Personal Life Investment

Middle-aged adults who report a high sense of control over events in various aspects of their lives—health, family, and work—also report more favorable psychological well-being. Sense of control contributes further to self-efficacy (Lang, 2016). It also predicts use of more effective coping strategies, including seeking social support, and thereby helps sustain a positive outlook in the face of health, family, and work difficulties (Lachman, Neupert, & Agrigoroaei, 2011).

Personal life investment—firm commitment to goals and involvement in pursuit of those goals—also adds to mental health and life satisfaction (Staudinger & Bowen, 2010). According to Mihaly Csikszentmihalyi, a vital wellspring of happiness is *flow*—the psychological state of being so engrossed in a demanding, meaningful activity that one loses all sense of time and self-awareness. People describe

ARTPARADIGM/DIGITAL VISION/GETTY IMAGES

Complex endeavors that offer potential for growth engender flow—a pleasurable psychological state of deep engrossment. The perseverance and skill essential for flow are well-developed at midlife.

flow as the height of enjoyment, even as an ecstatic state. The more people experience flow, the more they judge their lives to be gratifying (Nakamura & Csikszentmihalyi, 2009). Although flow is common in people engaged in creative endeavors, many others report it—

suicides among U.S. middle-aged adults rose by 25 percent. Currently, the suicide rate for middle-aged people nearly matches that of people 85 and older (whose rate is the highest). White men between 45 and 64 showed the sharpest rise, while also displaying elevated death rates from drug and alcohol abuse. Most were poorly educated, economically disadvantaged, and suffered from physical and mental health problems (American Society for Suicide Prevention, 2016; Centers for Disease Control and Prevention, 2016d). Although causes are not yet clear, experts speculate that these trends may reflect strengthening associations among poverty, declining health, and hopelessness in middle adulthood that are unique to the United States. Steady declines in midlife mortality occurred in Australia, Canada, and Western Europe during the same time period.

### Gender Identity

In her forties and early fifties, Trisha appeared more assertive at work. She spoke out more freely at meetings and took a leadership role when a team of lawyers worked on an especially complex case. She was also more dominant in family relationships, expressing her opinions to her husband and son more readily than she had 10 or 15 years earlier. In contrast, Devin's sense of empathy and caring became more apparent, and he was less assertive and more accommodating to Trisha's wishes than before.

Many studies report an increase in “masculine” traits in women and “feminine” traits in men across middle age. Women became more confident, self-sufficient, and forceful, men more emotionally sensitive, caring, considerate, and dependent. These

students who love studying, employees who like their jobs, adults involved in challenging leisure pursuits, and parents and grandparents engaged in pleasurable learning activities with children. Flow depends on perseverance and skill at complex endeavors that offer potential for growth (Rich, 2013). These qualities are well-developed in middle adulthood.

### Positive Social Relationships

Developing gratifying social ties is closely linked to midlife psychological well-being. High-quality relationships with relatives and friends improve mental health by promoting positive emotions and protecting against stress (Fiori, Antonucci, & Cortina, 2006; Fuller-Iglesias, Webster, & Antonucci, 2015). Enjoyable social ties can even strengthen the impact of an exercise regimen on well-being. Among an ethnically diverse sample of women using a private gym or an African Caribbean community center, exercising with likeminded companions contributed to happiness and life satisfaction (Wray, 2007). The social side of going to the gym appeared especially important to minority women, who were less concerned with physical-appearance benefits than their European-American agemates.

### A Good Marriage

Although support from relatives and friends is important, a good marriage boosts psycho-

logical well-being even more. The role of marriage in mental health increases with age, becoming a powerful predictor by late midlife (Marks & Greenfield, 2009; Rauer & Albers, 2016). U.S. middle-aged adults in cohabiting relationships do not necessarily benefit similarly. But in Western Europe, where cohabitation signifies high relationship commitment, cohabitators and married people report equally positive well-being (Hansen, Moum, & Shapiro, 2007).

Longitudinal research suggests that a good marriage actually brings about well-being. For example, in a British study of a nationally representative sample of middle-aged and older couples, marital adjustment more strongly predicted life satisfaction at a two-year follow-up than life satisfaction predicted later marital adjustment (Be, Whisman, & Uebelacker, 2013). And when interviews with over 13,000 U.S. adults were repeated five years later, people who remained married reported greater happiness than those who remained single (Marks & Lambert, 1998). Those who separated or divorced became less happy, reporting considerable depression.

Although not everyone is better off married, the link between marriage and well-being is similar in many nations, suggesting that marriage changes people's behavior in ways that make them better off (Diener et al., 2000). Married partners monitor each other's

health and offer care in times of illness. They also earn and save more money than single people, and income is linked to higher well-being (Sacks, Stevenson, & Wolfers, 2012). Furthermore, sexual satisfaction predicts mental health, and married couples have more satisfying sex lives than singles (see Chapter 13).

### Mastery of Multiple Roles

Success in handling multiple roles—spouse, parent, worker, community volunteer—is linked to psychological well-being. In the MIDUS survey, as role involvement increased, both men and women reported greater environmental mastery, more rewarding social relationships, heightened sense of purpose in life, and more positive emotion. Furthermore, adults who occupied multiple roles and who also reported high control (suggesting effective role management) scored especially high in well-being—an outcome that was stronger for less-educated adults (Ahrens & Ryff, 2006). Control over roles may be vital for individuals with lower educational attainment, whose role combinations may be particularly stressful and who have fewer economic resources.

Finally, among nonfamily roles, community volunteering in the latter part of midlife contributes uniquely to psychological well-being (Choi & Kim, 2011; Ryff et al., 2012). It may do so by strengthening self-efficacy, generativity, and altruism.

tendencies emerged in cross-sectional and longitudinal research, in people varying in SES, and in diverse cultures—not just Western industrialized nations but also village societies such as the Maya of Guatemala, the Navajo of the United States, and the Druze of the Middle East (Fry, 1985; Gutmann, 1977; James et al., 1995; Jones, Peskin, & Livson, 2011). Consistent with Levinson's theory, gender identity in midlife seemed to become more androgynous—a mixture of “masculine” and “feminine” characteristics.

But in more recently gathered self-reports, men's and women's endorsement of “masculine” and “feminine” traits showed little change throughout adulthood (Lemaster, Delaney, & Strough, 2015; Strough et al., 2007). Cohort effects may explain the contradictory findings: More recent participants were mostly adolescents or young adults during the women's movement of the

1970s and 1980s, or were born after it. Influenced by this time of major social change, adults of diverse ages—and especially women—may have been more likely than previous cohorts to endorse an androgynous mix of “masculine” and “feminine” traits.

The demands of middle age may help explain why, in a wealth of earlier research, it is associated with increased androgyny. For example, some evidence reveals a link between children's departure from the home and men's greater openness to the “feminine” side of their personalities (Huyck, 1998). Perhaps men's need to enrich a marital relationship after children depart, along with reduced chances for career advancement, prompt an awakening of emotionally sensitive traits. In other research, women who attained high status in their careers gained most in dominance, assertiveness, and outspokenness by their early

MORSA IMAGES/GETTY IMAGES

This middle-aged son comfortably expresses affection for his father. In midlife, men tend to show an increase in “feminine” traits, becoming more emotionally sensitive, caring, considerate, and dependent.

fifties (Wink & Helson, 1993). Also, midlife women are more likely than men to face economic and social disadvantages. A greater number remain divorced, are widowed, or encounter discrimination in the workplace. Self-reliance and assertiveness are vital for coping with these circumstances.

In sum, a complex combination of social roles and life conditions underlies the midlife rise in androgyny, which seems to have spread to other age periods in response to cultural changes favoring gender equality. In Chapter 8, we noted that androgyny predicts high self-esteem. In adulthood, it is also associated with cognitive flexibility, creativity, advanced moral reasoning, and psychosocial maturity (Prager & Bailey, 1985; Runco, Cramond, & Pagnani, 2010; Waterman & Whitbourne, 1982). People who integrate the masculine and feminine sides of their personalities tend to be psychologically healthier, perhaps because they are able to adapt more easily to life’s challenges.

## Individual Differences in Personality Traits

Although Trisha and Jewel both became more self-assured and assertive in midlife, in other respects they differed. Trisha had always been more organized and hard-working, Jewel more gregarious and fun-loving. Once, the two women traveled together. At the end of each day, Trisha was disappointed if she had not kept to a schedule and visited every tourist attraction. Jewel liked to “play it by ear”—wandering through streets and stopping to talk with shopkeepers and residents.

In previous sections, we considered personality changes common to many middle-aged adults, but stable individual differences also exist. Through factor analysis of self-report ratings, the hundreds of personality traits on which people differ have been reduced to five basic factors, often referred to as the **“big five” personality traits**: neuroticism, extroversion, openness to experience, agreeableness, and conscientiousness. Table 16.1 provides a description of each. Notice that Trisha is high in conscientiousness, whereas Jewel is high in extroversion.

Longitudinal and cross-sectional studies of U.S. men and women reveal that agreeableness and conscientiousness increase from adolescence through middle age, whereas neuroticism declines, and extroversion and openness to experience do not change or decrease slightly—changes that reflect “settling down” and greater maturity. Similar trends have been identified in more than 50 countries varying widely in cultural traditions, including Canada, Germany, Italy, Japan, Russia, and South Korea (McCrae & Costa, 2006; Roberts, Walton, & Viechtbauer, 2006; Schmitt et al., 2007; Soto et al., 2011; Srivastava et al., 2003).

The consistency of these cross-cultural findings has led some researchers to conclude that adult personality change is genetically influenced. They also note that individual differences in the “big five” traits are large and highly stable: A person who scores high or low at one age is likely to do the same at another, over intervals ranging from 3 to 30 years (McCrae & Costa, 2006).

**TABLE 16.1**  
The “Big Five” Personality Traits

TRAIT	DESCRIPTION
Neuroticism	Individuals who are high on this trait are worrying, temperamental, self-pitying, self-conscious, emotional, and vulnerable. Individuals who are low are calm, even-tempered, self-content, comfortable, unemotional, and hardy.
Extroversion	Individuals who are high on this trait are affectionate, talkative, active, fun-loving, and passionate. Individuals who are low are reserved, quiet, passive, sober, and emotionally unreactive.
Openness to experience	Individuals who are high on this trait are imaginative, creative, original, curious, and liberal. Individuals who are low are down-to-earth, uncreative, conventional, uncurious, and conservative.
Agreeableness	Individuals who are high on this trait are soft-hearted, trusting, generous, acquiescent, lenient, and good-natured. Individuals who are low are ruthless, suspicious, stingy, antagonistic, critical, and irritable.
Conscientiousness	Individuals who are high on this trait are conscientious, hard-working, well-organized, punctual, ambitious, and persevering. Individuals who are low are negligent, lazy, disorganized, late, aimless, and nonpersistent.

Source: McCrae & Costa, 2006; Soto, Kronauer, & Liang, 2016.

How can there be high stability in personality traits, yet significant changes in aspects of personality discussed earlier? Look closely at the “big five” traits in Table 16.1, and you will see that they differ from the attributes considered in previous sections: They do not take into account motivations, preferred tasks, and coping styles, nor do they consider how certain aspects of personality, such as masculinity and femininity, are integrated. Theorists concerned with change due to experience focus on how personal needs and life events induce new strategies and goals; their interest is in “the human being as a complex adaptive system” (Block, 2011, p. 19). In contrast, those who emphasize stability due to heredity measure personality traits on which individuals can easily be compared and that are present at any time of life.

To resolve this apparent contradiction, we can think of adults as changing in overall organization and integration of personality as they adapt to changing life circumstances but doing so on a foundation of basic, enduring dispositions. But even the “big five” traits are responsive to life experiences: For example, people in stable jobs and romantic relationships, compared to those without these commitments, show greater gains in conscientiousness and agreeableness and declines in neuroticism over time (Hudson & Fraley, 2016; Lodi-Smith & Roberts, 2007). These findings confirm that personality remains an “open system,” responsive to the pressures of life experiences.

## Ask yourself

**CONNECT** List cognitive gains that typically occur during middle adulthood. (See Chapter 15, pages 524–526 and 530–531.) How might they support midlife personality changes?

**APPLY** Jeff, age 46, suggested to his wife, Julia, that they set aside time once a year to discuss their relationship—both positive aspects and ways to improve. Julia was surprised because Jeff had never before expressed interest in working on their marriage. What midlife developments probably fostered this new concern?

**REFLECT** List your hoped-for and feared possible selves. Then ask family members in early and middle adulthood to do the same. Are their reports consistent with age-related research findings? Explain.

## Relationships at Midlife

**16.6** Describe the middle adulthood phase of the family life cycle, including marriage, divorce, parent–child relationships, and grandparenthood.

**16.7** Describe midlife sibling relationships and friendships.

The emotional and social changes of midlife take place within a complex web of family relationships and friendships and an intensified personal focus on generative concerns. Although some middle-aged people live alone, the vast majority—about 90 percent in the United States—live in families, about 65

percent with a spouse, 15 percent with a cohabiting partner, and 10 percent as unmarried or formerly married adults residing with children and/or other relatives (U.S. Census Bureau, 2016a). Partly because they have ties to older and younger generations in their families and partly because their friendships are well-established, midlife adults have a larger number of close relationships than adults of other age periods do (Antonucci, Akiyama, & Takahashi, 2004).

The middle adulthood phase of the family life cycle is often referred to as “launching children and moving on.” In the past, it was called the “empty nest,” but this phrase implies a negative transition, especially for women who have devoted themselves entirely to their children and for whom the end of active parenting can trigger feelings of emptiness and regret. But for most people, middle adulthood is a liberating time, offering a sense of completion and opportunities to strengthen social ties and rekindle interests.

As our discussion in Chapter 14 revealed, increasing numbers of young adults are living at home due to role transitions and financial challenges, yielding launch–return–relaunch patterns for many middle-aged parents. Still, a declining birthrate and longer life expectancy mean that many contemporary parents do launch children a decade or more before retirement and then turn to other rewarding activities. As adult children depart and marry, middle-aged parents must adapt to new roles of parent-in-law and grandparent. At the same time, they must establish a different type of relationship with their aging parents, who may become ill or infirm and die.

Middle adulthood is marked by the greatest number of exits and entries of family members. Let’s see how ties within and beyond the family change during this time of life.

## Marriage and Divorce

Although not all couples are financially comfortable, middle-aged households are well-off economically compared with other age groups. Americans between 45 and 54 have the highest average annual income, and contemporary middle-aged adults—more of whom have earned college and postgraduate degrees and live in dual-earner families—are financially better off than previous midlife generations (U.S. Census Bureau, 2016a). Partly because of increased education and financial security, the contemporary social view of marriage in midlife is one of expansion and new horizons.

These forces strengthen the need to review and adjust the marital relationship. For Devin and Trisha, this shift was gradual. By middle age, their marriage had permitted satisfaction of family and individual needs, endured many changes, and culminated in deeper feelings of love. Elena’s marriage, in contrast, became more conflict-ridden as her teenage daughter’s problems introduced added strains and as departure of children made marital difficulties more obvious. Tim’s failed marriage revealed yet another pattern. With passing years, the number of problems declined, but so did the love expressed (Gottman & Gottman, 2015; Rokach, Cohen, & Dreman, 2004). As less happened in the

LORI ADAMSKI PEEK/WORKBOOK STOCK/GETTY IMAGES

For many middle-aged couples, having forged a relationship that permits satisfaction of both family and individual needs results in deeper feelings of love.

relationship, good or bad, the couple had little to keep them together.

As the Biology and Environment box on pages 546–547 revealed, marital satisfaction is a powerful predictor of midlife psychological well-being. Marital happiness is more strongly associated with life satisfaction than happiness in other domains, including vocation, children, friendships, and health (Fleeson, 2004; Heller, Watson, & Ilies, 2004). Consequently, middle-aged men who have focused mostly on career often realize the limited nature of their pursuits. At the same time, women may insist on a more gratifying relationship. And having grown children who are engaged in adult roles reminds middle-aged parents that they are in the latter part of their lives, prompting many to decide that the time for improving their marriages is now.

As with early adulthood, evidence on same-sex middle-aged couples is scarce. But some research suggests that compared to other couples, lesbian partners use more effective communication styles (Zdaniuk & Smith, 2016). In interviews with over 200 heterosexual and same-sex couples in their forties, fifties, and sixties, the lesbian couples described more openness and honesty in sharing thoughts and feelings with their partner (Mackey, Diemer, & O'Brien, 2000). Across heterosexual, lesbian, and gay participants, physical affection, low conflict, and sense of fairness predicted a deeper sense of psychological intimacy.

Divorce has increasingly become a route to resolving an unsatisfactory marriage in midlife. Although the overall U.S. divorce rate has declined over the past two decades, the divorce rate of U.S. adults age 50 and older has doubled over this period (Brown & Lin, 2013). A longer life expectancy, widespread

social acceptance of marital breakup, and greater financial security (making it easier to leave an unhappy marriage) have contributed to this surge in later-life divorces.

Divorce at any age takes a heavy psychological toll, but midlifers seem to adjust more easily than younger people. A survey of more than 13,000 Americans revealed that following divorce, middle-aged men and women reported less decline in psychological well-being than their younger counterparts (Marks & Lambert, 1998). Midlife gains in practical problem solving and effective coping strategies may reduce the stressful impact of divorce.

Still, individual differences in adjustment exist, with middle-aged adults who end a highly distressed marriage faring best (Amato, 2010). Many ultimately report gains in happiness—an outcome stronger among women than men (Bourassa, Sbarra, & Whisman, 2015). In Chapter 14, we saw that women's happiness suffers more than men's in a poor-quality marriage with unequal sharing of authority and responsibilities. When these and other relationship difficulties cannot be solved, divorce eventually brings emotional relief.

What do recently divorced middle-aged people say about why their marriages ended? Women frequently mention communication problems, inequality in the relationship, adultery, gradual distancing, substance abuse, physical and verbal abuse, or their own desire for autonomy. Men also bring up poor communication, and they sometimes admit that their “workaholic” lifestyle or emotional inattentiveness played a major role in the marital failure. Women are more likely than men to initiate divorce, and those who do fare somewhat better in psychological well-being (Sakraida, 2005; Schneller & Arditto, 2004). Men who initiate a split often already have another romantic involvement to turn to.

Because the divorce rate is greater among remarried couples than those in first marriages, about half of midlife divorces involve people who have had one or more previous unsuccessful marriages. Although many middle-aged divorcing adults are in comfortable economic circumstances, for a considerable number of women, marital breakup—especially when it is repeated—severely reduces standard of living (see pages 353–354 in Chapter 10). Consequently, in midlife and earlier, divorce contributes to the **feminization of poverty**—a trend in which women who support themselves or their families have become the majority of the adult population living in poverty, regardless of age and ethnic group. The gender gap in poverty has declined in Western nations, due to women's increased labor market participation, a reduction in the gender pay gap (see page 499 in Chapter 14), and public policies supporting women and families. But because of weaker U.S. public policies (see Chapter 2), the gender gap in poverty remains higher in the United States than in other Western countries (Kim & Choi, 2013).

Longitudinal evidence reveals that middle-aged women who weather divorce successfully tend to become more tolerant, comfortable with uncertainty, nonconforming, and self-reliant in personality—factors believed to be fostered by divorce-forced independence. And both men and women reevaluate what they

consider important in a healthy relationship, placing greater weight on equal friendship and less on passionate love than they had the first time. As in earlier periods, divorce represents both a time of trauma and a time of growth (Baum, Rahav, & Sharon, 2005; Lloyd, Sailor, & Carney, 2014; Schneller & Arditti, 2004). Less is known about long-term adjustment following divorce among middle-aged men, perhaps because most enter new relationships and remarry within a short time.

## Changing Parent–Child Relationships

Parents' positive relationships with their grown children are the result of a gradual process of "letting go," starting in childhood, gaining momentum in adolescence, and culminating in children's independent living. As noted earlier, most parents "launch" adult children sometime in midlife. But because more people are delaying having children to their thirties and even forties (see page 444 in Chapter 13), the age at which midlifers experience their children's departure varies widely. Most parents adjust well; only a minority have difficulty. Investment in nonparental relationships and roles, children's characteristics, parents' marital and economic circumstances, and cultural forces affect the extent to which this transition is expansive and rewarding or sad and distressing.

After their son Mark secured a career-entry job and moved out of the family home permanently, Devin and Trisha felt a twinge of nostalgia combined with a sense of pride in their grown son's maturity and success. Beyond this, they returned to rewarding careers and community participation and delighted in having more time for each other. Parents who have developed gratifying alternative activities typically welcome their children's adult status (Mitchell & Lovegreen, 2009). A strong work orientation, especially, predicts gains in life satisfaction after children depart from the home.

Wide cultural variations exist in the social clock for children's departure. Recall from Chapter 13 that many young people from low-SES homes and with cultural traditions of extended-family living do not leave home early. In the Southern European countries of Greece, Italy, and Spain, parents often actively delay their children's leaving. In Italy, for example, parents believe that moving out without a "justified" reason, usually marriage, signifies that something is wrong in the family. At the same time, Italian adults grant their grown children extensive freedom (Crocetti, Rabaglietti, & Sica, 2012). Parent–adult-child relationships are usually positive, making living with parents attractive.

With the end of parent–child coresidence comes a substantial decline in parental authority. Devin and Trisha no longer knew of Mark's daily comings and goings or expected him to inform them. Nevertheless, like most young adults, Mark visited regularly and telephoned, texted, and e-mailed often to report on events in his life, seek advice, and keep abreast of his parents' lives. Although the parental role changes, its continuation is important to middle-aged adults. Departure of children is a relatively minor event as long as parent–child contact and pleasurable

interaction are sustained (Fingerman et al., 2016; Mitchell & Lovegreen, 2009). When communication seldom occurs or is negative, parents' psychological well-being declines.

Whether or not they reside with parents, young-adult children who are "off-time" in development—who deviate from parental expectations about how the path to adult responsibilities should unfold—can prompt parental strain (Settersten, 2003). Consider Elena, whose daughter was doing poorly in her college courses and in danger of not graduating. The need for extensive parental guidance, at a time when she expected her daughter to be more responsible and independent, caused anxiety and unhappiness for Elena, who was ready to reduce time devoted to active parenting.

In one study, researchers asked a large sample of 40- to 60-year-old parents to report on their grown children's problems and successes along with their own psychological well-being. Consistent with the familiar saying, "parents are only as happy as their least happy child," having even one problematic child dampened parents' well-being, but having a successful child did not have a compensating positive effect. The more grown children with problems, the poorer parents' well-being (Fingerman et al., 2012a). In contrast, it took multiple successful grown children to sway parents' well-being in a favorable direction. As with marriages, negative, conflict-ridden experiences with grown children are particularly salient, profoundly affecting midlife parents' psychological states.

Throughout middle adulthood, parents continue to give more assistance to children than they receive, especially while children are unmarried or when they face difficulties, such as marital breakup or unemployment (Ploeg et al., 2004; Zarit & Eggebeen, 2002). Support in Western countries typically flows "downstream": Although ethnic variations exist, most middle-aged parents provide more financial, practical, emotional, and social support to their offspring than to their aging parents, unless a parent has an urgent need (declining health or other crises) (Fingerman & Birditt, 2011; Fingerman et al., 2011a). In explaining their generous support of adult children, parents usually mention the importance of the relationship. And providing adult children with assistance enhances midlife psychological well-being (Marks & Greenfield, 2009). Clearly, middle-aged adults remain invested in their adult children's development and continue to reap deep personal rewards from the parental role.

However, the amount and type of support middle-aged adults provide vary with SES. Parents with more education and income give more financial assistance (Fingerman et al., 2012b). But low-SES parents give more overall support, usually consisting of coresidence plus various types of intangible assistance—advice, help with child care, emotional encouragement, and companionship. Nevertheless, because of widespread single parenthood plus larger families, low-SES parents must divide their supportive resources among more offspring. Consequently, on average, low-SES parents are able to give less tangible and intangible support to each child than their higher-SES counterparts (Fingerman et al., 2015). Finding themselves devoting much time to giving support that is thinly spread and, therefore, less effective in

## Applying what we Know

### Ways Middle-Aged Parents Can Promote Positive Ties with Their Adult Children

SUGGESTION	DESCRIPTION
Emphasize positive communication.	Let adult children and their intimate partners know of your respect, support, and interest. This not only communicates affection but also permits conflict to be handled in a constructive context.
Avoid unnecessary comments that are a holdover from childhood.	Adult children, like younger children, appreciate an age-appropriate relationship. Comments that have to do with safety, eating, and self-care (“Be careful on the freeway,” “Don’t eat those foods,” “Make sure you wear a sweater—it’s cold out today”) annoy adult children and can stifle communication.
Accept the possibility that some cultural values and practices and aspects of lifestyle will be modified in the next generation.	In constructing a personal identity, most adult children have gone through a process of evaluating the meaning of cultural values and practices for their own lives. Traditions and lifestyles cannot be imposed on adult children.
When an adult child encounters difficulties, resist the urge to “fix” things.	Accept the fact that no meaningful change can take place without the willing cooperation of the adult child. Stepping in and taking over communicates a lack of confidence and respect. Find out whether the adult child wants your help, advice, and decision-making skills.
Be clear about your own needs and preferences.	When it is difficult to arrange for a visit, babysit, or provide other assistance, say so and negotiate a reasonable compromise rather than letting resentment build.

helping children launch their lives is likely draining and disappointing to many low-SES parents.

After children marry, parents must adjust to an enlarged family network that includes in-laws. Difficulties occur when parents do not approve of their child’s partner or when the young couple adopts a way of life inconsistent with parents’ values. Parents who take steps to forge a positive tie with a future daughter- or son-in-law generally experience a closer relationship after the couple marries (Fingerman et al., 2012d). And when warm, supportive relationships endure, intimacy between parents and children increases over the adult years, with great benefits for parents’ life satisfaction (Ryff, Singer, & Seltzer, 2002). Members of the middle generation, especially mothers, usually take on the role of **kinkeeper**, gathering the family for celebrations and making sure everyone stays in touch.

Parents of adult children expect a mature relationship, marked by tranquility and contentment. Yet many factors—on both the child’s and the parent’s sides and also having to do with family circumstances—affect whether that goal is achieved. Applying What We Know above suggests ways middle-aged parents can increase the chances that bonds with adult children will be loving and rewarding and serve as contexts for personal growth.

## Grandparenthood

Two years after Mark married, Devin and Trisha were thrilled to learn that a granddaughter was on the way. Compared with a generation ago, the arrival of grandparenthood occurs a decade or more later, due to postponement of marriage and childbearing. Currently, the average age of becoming a grandparent for U.S. women is 49; for U.S. men, 52. In Canada and many Western

European nations, grandparenthood is further delayed, to the mid- to late fifties, likely because of factors linked to reduced childbearing, including lower rates of poverty, unintended births, and religiosity (Leopold & Skopek, 2015; Margolis, 2016). Yet a longer life expectancy means that many adults will spend one-third or more of their lifespan in the grandparent role.

**Meanings of Grandparenthood.** Middle-aged adults typically rate grandparenthood as highly important, following closely behind the roles of parent and spouse but ahead of worker, son or daughter, and sibling (Reitzes & Mutran, 2002). Why did Trisha and Devin, like many others their age, greet the announcement of a grandchild with such enthusiasm? Most people experience grandparenthood as a significant milestone, mentioning one or more of the following gratifications:

- *Valued older adult*—being perceived as a wise, helpful person
- *Immortality through descendants*—leaving behind not just one but two generations after death
- *Reinvolvement with personal past*—being able to pass family history and values to a new generation
- *Indulgence*—having fun with children without major child-rearing responsibilities (Hebblethwaite & Norris, 2011)

**Grandparent–Grandchild Relationships.** Grandparents’ styles of relating to grandchildren vary as widely as the meanings they derive from their new role. The grandparent’s and grandchild’s age and sex make a difference. When their granddaughter was young, Trisha and Devin enjoyed an affectionate, playful relationship with her. As she got older, she looked to

them for information and advice in addition to warmth and caring. By the time their granddaughter reached adolescence, Trisha and Devin had become role models, family historians, and conveyers of social, vocational, and religious values.

Living nearby is the strongest predictor of frequent, face-to-face interaction with young grandchildren and a major contributor to feelings of closeness with older grandchildren. Despite high family mobility in Western industrialized nations, most grandparents live near enough to at least one grandchild to enable regular visits. But because time and resources are limited, number of “grandchild sets” (households with grandchildren) reduces grandparent visits (Bangerter & Waldron, 2014; Uhlenberg & Hammill, 1998). A strong desire to affect the development of grandchildren can motivate grandparents’ involvement. As grandchildren get older, distance becomes less influential and relationship quality more so: The extent to which adolescent or young-adult grandchildren believe their grandparent values contact is a good predictor of a close bond (Brussoni & Boon, 1998).

Maternal grandmothers report more frequent visits with grandchildren than do paternal grandmothers, who are slightly advantaged over both maternal and paternal grandfathers (Uhlenberg & Hammill, 1998). Typically, relationships are closer between grandparents and grandchildren of the same sex and, especially, between maternal grandmothers and granddaughters—a pattern found in many countries (Brown & Rodin, 2004). Grandmothers also report higher satisfaction with the grandparent role than grandfathers, perhaps because grandmothers

are more likely to participate in recreational, religious, and family activities with grandchildren (Reitzes & Mutran, 2004; Silverstein & Marengo, 2001). The grandparent role may be a vital means through which women satisfy their kinkeeping function.

SES and ethnicity also influence grandparent–grandchild ties. In higher-income families, where the grandparent role is not central to family maintenance and survival, it is fairly unstructured and takes many forms. In low-income families, by contrast, grandparents often perform essential activities. For example, many single parents live with their families of origin and depend on grandparents’ assistance, including help with caregiving, to reduce the impact of poverty (Masten, 2013). As children experience family stressors, bonds with grandparents can take on increasing importance, serving as a vital source of resilience.

In cultures that stress interdependence among generations of family members, grandparents are absorbed into an extended-family household and often become actively involved in child rearing. When a Chinese, Korean, or Mexican-American maternal grandmother is a homemaker, she is the preferred caregiver while parents of young children are at work (Low & Goh, 2015; Williams & Torrez, 1998). Similarly, involvement in child care is high among Native-American grandparents. In the absence of a biological grandparent, an unrelated aging adult may be integrated into the family to serve as a mentor and disciplinarian for children (Werner, 1991). (See Chapter 2, page 63, for a description of the grandmother’s role in the African-American extended family.)

Increasingly, grandparents have stepped in as primary caregivers in the face of serious family problems. As the Social Issues: Health box on page 554 reveals, a rising number of American children live apart from their parents in grandparent-headed households. Despite their willingness to help and their competence at child rearing, grandparents who take full responsibility for young children experience considerable emotional and financial strain. They need more assistance from community and government agencies than is currently available.

Because parents usually serve as gatekeepers of grandparents’ contact with grandchildren, relationships between grandparents and their daughter-in-law or son-in-law strongly affect the closeness of grandparent–grandchild ties. A positive bond with a daughter-in-law seems particularly important in the relationship between grandparents and their son’s children (Fingerman, 2004; Sims & Rofail, 2013). And after a marital breakup, grandparents who are related to the custodial parent (typically the mother) have more frequent contact with grandchildren.

When family relationships are positive, grandparenthood provides an important means of fulfilling personal and societal needs in midlife and beyond. Typically, grandparents are a frequent source of pleasure, support, and knowledge for children, adolescents, and young adults. They also provide the young with firsthand experience in how older people think and function. In return, grandchildren become deeply attached to grandparents and keep them abreast of social change. Clearly, grandparenthood is a vital context for sharing between generations.

Many grandparents derive great joy from an affectionate, playful relationship with young grandchildren. As this grandchild gets older, he may look to his grandfather for advice, as a role model, and for family history.

## Social Issues: Health

### Grandparents Rearing Grandchildren: The Skipped-Generation Family

**N**early 2.7 million U.S. grandparents live with grandchildren but apart from the children's parents in **skipped-generation families** (Ellis & Simmons, 2014). The number of grandparents with primary responsibility for rearing grandchildren has increased over the past two decades, with an especially sharp rise during the economic recession of 2007 to 2009. The arrangement occurs in all ethnic groups, but more often in African-American, Hispanic, and Native-American families than in European-American families. Although grandparent caregivers are more likely to be women than men, many grandfathers participate (Fuller-Thomson & Minkler, 2005, 2007). Grandparents generally step in when parents' troubled lives—severe financial hardship, substance abuse, child abuse and neglect, family violence, or physical or mental illness—threaten children's safety and security (Smith, 2016). Often these families take in two or more children.

As a result, grandparents usually assume the parenting role under highly stressful life circumstances. Unfavorable child-rearing experiences have left their mark on the children, who show high rates of learning difficulties, depression, and antisocial behavior. Absent parents' adjustment difficulties strain family relationships. Parents may interfere by violating the grandparents' behavioral limits, taking grandchildren away without permission, or making promises to children that they do not keep. These children also introduce financial burdens into households that often are already low-income (Hayslip, Blumenthal, & Garner, 2014; Henderson & Bailey, 2015). All these factors heighten grandparents' emotional distress.

Grandparents struggle with daily dilemmas—wanting to be grandparents, not parents; wanting the parent to be present in the child's life but fearing for the child's well-being if the parent returns and does not provide good care (Templeton, 2011). And grandparent caregivers, at a time when they anticipated having more time for spouses, friends, and leisure, instead have less. Many report feeling emotionally drained, depressed, and worried about what will happen to the children if their own health fails (Henderson & Bailey, 2015). Some families are extremely burdened. Native-American caregiving grandparents are especially likely to be unemployed, to have a disability, to be caring for several grandchildren, and to be living in extreme poverty (Fuller-Thomson & Minkler, 2005).

Despite great hardship, these grandparents seem to realize their widespread image as “silent saviors,” often forging close emotional bonds with their grandchildren and using effective child-rearing practices (Gibson, 2005). Compared with children in divorced, single-parent families, blended families, or foster families, children reared by grandparents fare better in adjustment (Rubin et al., 2008; Solomon & Marx, 1995).

Skipped-generation families have a tremendous need for social and financial support and intervention services for troubled children. Custodial grandparents with relatives and friends they can count on benefit in physical and mental health (Hayslip, Blumenthal, & Garner, 2015). Others say that support

ELLEN B. SEMSI

Although custodial grandparents usually assume the parenting role under highly stressful circumstances, most find compensating rewards in rearing grandchildren.

groups—for themselves and for their grandchildren—are especially helpful, yet only a minority make use of such interventions (Smith, Rodriguez, & Palmieri, 2010). This suggests that grandparents need special help in finding out about and accessing support services.

Although their everyday lives are often stressful, caregiving grandparents—even those rearing children with serious problems—report as much fulfillment in the grandparent role as typical grandparents do (Hayslip & Kaminski, 2005). The warmer the grandparent–grandchild bond, the greater grandparents' long-term life satisfaction (Goodman, 2012). Many grandparents mention joy from sharing children's lives and feelings of pride at children's progress, which help compensate for difficult circumstances. And some grandparents view the rearing of grandchildren as a “second chance”—an opportunity to make up for earlier, unfavorable parenting experiences and “do it right” (Dolbin-MacNab, 2006).

### Middle-Aged Children and Their Aging Parents

The number of middle-aged Americans with at least one living parent has risen dramatically—from 10 percent in 1900 to more than 60 percent today (Wiemers & Bianchi, 2015). A longer life expectancy means that adult children and their parents are

increasingly likely to grow old together. What are middle-aged children's relationships with their aging parents like? And how does life change for adult children when an aging parent's health declines?

**Frequency and Quality of Contact.** A widespread myth is that adults of past generations were more devoted than today's

adults to their aging parents. Although adult children spend less time in physical proximity to their parents, the reason is not neglect or isolation. Because of a desire to be independent, made possible by gains in health and financial security, fewer aging adults live with younger generations now than in the past. Nevertheless, nearly two-thirds of older adults in the United States live close to at least one of their children, and frequency of contact is high through both visits and telephone calls (U.S. Department of Health and Human Services, 2016b). Proximity increases with age: Aging adults who move usually do so in the direction of kin, and younger people tend to move in the direction of their aging parents.

Middle age is a time when adults reassess relationships with their parents, just as they rethink other close ties. Many adult children become more appreciative of their parents' strengths and generosity and mention positive changes in the quality of the relationship, even after parents show physical declines. A warm, enjoyable relationship contributes to both parent and adult-child well-being (Fingerman et al., 2007, 2008; Pudrovskaya, 2009). Trisha, for example, felt closer to her parents and often asked them to tell her more about their earlier lives.

Middle-aged daughters forge closer, more supportive relationships with aging parents, especially mothers, than do middle-aged sons (Suitor, Gilligan, & Pillemer, 2015). But this gender difference may be declining. Sons report closer ties and greater assistance to aging parents in recent than in previous studies. Changing gender roles are likely responsible. Because the majority of contemporary middle-aged women are employed, they face many competing demands on their time and energy. Consequently, men are becoming more involved in family responsibilities, including with aging parents (Fingerman & Birditt, 2011; Pew Research Center, 2013c). Despite this shift, women's investment continues to exceed men's.

In cultures that emphasize interdependence, parents often live with their married children. For example, traditionally, Chinese, Japanese, and Korean aging parents moved in with a son and his wife, who tended to her in-laws' needs; today, many parents live with a daughter and her family, too. This tradition of coresidence, however, is declining in some parts of Asia and in the United States, as more Asian and Asian-American aging adults choose to live on their own. And in a growing number of these families, both the husband's and wife's aging parents receive support, though a bias toward providing greater practical and financial help to the son's parents remains (Davey & Takagi, 2013; Kim et al., 2015; Zhang, Gu, & Luo, 2014). In African-American and Hispanic families as well, coresidence is common. Regardless of whether coresidence and daily contact are typical, relationship quality usually reflects patterns established earlier: Positive parent-child ties generally remain so, as do conflict-ridden interactions.

Help exchanged between adult children and their aging parents is responsive to past and current family circumstances. The more positive the history of the parent-child tie, the more help given and received. Also, aging parents give more help to unmarried adult children and to those with disabilities. Similarly, adult children give more practical help and emotional support to aging

SOULINA IMAGES/THE IMAGE BANK/GETTY IMAGES

In midlife, many adults develop warmer, more supportive relationships with their aging parents. At a birthday party for her mother, this daughter expresses love and appreciation for her mother's strengths and generosity.

parents who are widowed or in poor health (Suitor et al., 2016). At the same time, middle-aged adults do what they can to maximize the overall quantity of help offered, as needed: While continuing to provide generous assistance to their children because of the priority placed on the parent-child tie (see page 551), midlifers augment the aid they give to their parents as parental health problems increase (Stephens et al., 2009).

Even when parent-child relationships have been emotionally distant, many adult children offer more support as parents age, out of a sense of altruism and family duty. And parent-child bonds often become closer as parents get older (Fingerman et al., 2011a; Ward, Spitz, & Deane, 2009).

In sum, as long as multiple roles are manageable and the experiences within each are generally positive, midlife intergenerational assistance as family members (aging parents) have increased needs is best characterized as *resource expansion* rather than as merely conflicting demands that inevitably drain energy and detract from psychological well-being (Pew Research Center, 2013c; Stephens et al., 2009). Recall from the Biology and Environment box on pages 546–547 that midlifers derive great personal benefits from successfully managing multiple roles. Their enhanced self-esteem, mastery, and sense of meaning and purpose expand their motivation and energy to handle added family-role demands, from which they reap additional personal rewards.

**Caring for Aging Parents.** About one-fourth of U.S. adult children provide unpaid care to an ill or disabled aging adult (Stepler, 2015). The burden of caring for aging parents can be great. In Chapter 2, we noted that as birthrates have declined, the family structure has become increasingly “top-heavy,” with more generations alive but fewer younger members. Consequently, more than one older family member is likely to need assistance, with fewer younger adults available to provide it.

The term **sandwich generation** is widely used to refer to the idea that middle-aged adults must care for multiple generations above and below them at the same time. Although only a

minority of contemporary middle-aged adults who care for aging parents have children younger than age 18 at home, many are providing assistance to young-adult children and to grandchildren—obligations that, when combined with work and community responsibilities, can lead middle-aged caregivers to feel “sandwiched,” or squeezed, between the pressures of older and younger generations. As more baby boomers move into late adulthood and as their adult children continue to delay childbearing, the number of midlifers who are working, rearing children, and caring for aging parents will increase.

Middle-aged adults living far from aging parents who are in poor health often substitute financial help for direct care, if they have the means. But when parents live nearby and have no spouse to meet their needs, adult children usually engage in direct care. Regardless of family income level, African-American, Asian-American, and Hispanic adults give aging parents more direct care and financial help than European-American adults do. And compared with their white counterparts, African Americans and Hispanics express a stronger sense of obligation, and find it more personally rewarding, to support their aging parents (Fingerman et al., 2011b; Roth et al., 2015; Shuey & Hardy, 2003). African Americans often draw on close, family-like relationships with friends and neighbors for caregiving assistance.

In all ethnic groups, responsibility for providing care to aging parents falls more on daughters than on sons. Why are women usually the principal caregivers? Families turn to the person who seems most available—living nearby and with fewer commitments that might interfere with the ability to assist. These unstated rules, in addition to parents’ preference for same-sex caregivers (aging mothers live longer), lead more women to fill the role (see Figure 16.4). Daughters also feel more obligated than sons to care for aging parents (MetLife, 2011a; Pillemer & Suito, 2013; Suito et al., 2015). And although couples strive to be fair to both sides of the family, they tend to provide more direct care for the wife’s parents. This bias, however, is weaker in ethnic minority families and not evident in Asian nations with cultural traditions specifying that daughters-in-law provide care to their husband’s parents (Chu, Xie, & Yu, 2011; Shuey & Hardy, 2003).

As Figure 16.4 shows, nearly one-fourth of American working women are caregivers; others quit their jobs to provide care. And the time they devote to caring for a chronically ill or disabled aging parent is substantial, averaging 20 hours per week (AARP, 2015; MetLife, 2011a). Nevertheless, men—although doing less than women—do contribute. In one investigation, employed men spent an average of 7½ hours per week caring for parents or parents-in-law (Neal & Hammer, 2007). Tim, for example, looked in on his father, a recent stroke victim, every evening, reading to him, running errands, making household repairs, and taking care of finances. His sister, however, provided more hands-on care—cooking, feeding, bathing, managing medication, and doing laundry. The care sons and daughters provide tends to be divided along gender-role lines. About 10 percent of the time—generally when no other family member can do so—sons become primary caregivers, heavily involved in basic-care tasks (Pinquart & Sörensen, 2006).

As adults move from early to later middle age, the sex difference in parental caregiving declines. Perhaps as men reduce their vocational commitments and feel less need to conform to a “masculine” gender role, they grow more able and willing to provide basic care (Marks, 1996; MetLife, 2011a). At the same time, parental caregiving may contribute to men’s greater openness to the “feminine” side of their personalities. A man who cared for his mother, severely impaired by dementia, commented on how the experience altered his outlook: “When this caregiving journey started, I felt scared and unprepared. Now I feel privileged and empowered. I feel fortunate to be able to hold my mom and kiss her . . . she continues to teach me, every day” (Colbert, 2014).

Most adult children help willingly, and many benefit personally (Brown & Brown, 2014). At the same time, caring for a chronically ill or disabled parent is highly stressful. Over time, the parent usually gets worse, and the caregiving task escalates. As Tim explained to Devin and Trisha, “One of the hardest aspects is the emotional strain of seeing my father’s physical and mental decline up close.”

Caregivers who share a household with ill parents—about 23 percent of U.S. adult children—experience the most stress. When a parent and child who have lived separately for years must move in together, conflicts generally arise over routines and lifestyles. But the greatest source of stress is problem behavior, especially for caregivers of parents who have deteriorated mentally (Bastawrous et al., 2015). Tim’s sister reported that their father would wake during the night, ask repetitive questions, follow her around the house, and become agitated and combative.

Parental caregiving often has emotional, physical, and financial consequences. It leads to role overload, high job

**FIGURE 16.4** Baby boomers, by work status and gender, who provide basic personal care to an aging parent in poor health. A survey of a nationally representative sample of 1,100 U.S. men and women over age 50 with at least one parent living revealed that more nonworking than working adults engaged in basic personal care (assistance with such activities as dressing, feeding, and bathing). Regardless of work status, many more women than men were caregivers. (Adapted from *The MetLife Study of Caregiving Costs to Working Caregivers: Double Jeopardy for Baby Boomers Caring for Their Parents*, June 2011, Figure 3. As midlife progresses, more men become involved in caring for an aging parent with a chronic illness or disability. Although the experience is stressful, most help willingly and benefit personally, perhaps becoming more open to the “feminine” side of their personalities.

absenteeism, exhaustion, inability to concentrate, feelings of hostility, anxiety about aging, and high rates of depression, with women more profoundly affected than men (Pinquart & Sörensen, 2006; Wang & Shi, 2016). Caregivers who must reduce their employment hours or leave the labor force to provide care (mostly women) face not just lost wages but also diminished retirement benefits. Despite having more time to care for an ill parent, women who quit work fare especially poorly in adjustment, probably because of social isolation and financial strain (Bookman & Kimbrel, 2011). Positive experiences at work can actually reduce the stress of parental care as caregivers bring a favorable self-evaluation and a positive mood home with them.

In cultures and subcultures where adult children feel an especially strong sense of obligation to care for aging parents, the emotional toll is also high (Knight & Sayegh, 2010). In research on Korean, Korean-American, and European-American caregivers of parents with mental disabilities, the Koreans and Korean Americans reported higher levels of family obligation and care burden—and also higher levels of anxiety and depression—than the European Americans (Lee & Farran, 2004; Youn et al., 1999). And among African-American caregivers, women who strongly endorsed cultural reasons for providing care (“It’s what my people have always done”) fared less well in mental health two years later than women who moderately endorsed cultural reasons (Dilworth-Anderson, Goodwin, & Williams, 2004).

Social support is highly effective in reducing caregiver stress. Tim’s encouragement, assistance, and willingness to listen helped his sister cope with in-home care of their father so that she could find satisfactions in it. When caregiving becomes a team effort with multiple family members trading off, caregivers cope more effectively. Under these conditions, despite being demanding and stressful, it can enhance psychological well-being (Roberto & Jarrott, 2008; Roth et al., 2015). Adult children feel gratified at having helped and gain in self-understanding, problem solving, sense of competence, and appreciation of life’s meaning.

## LOOK and LISTEN

Ask a middle-aged adult caring for an aging parent in declining health to describe both the stressful and rewarding aspects of caregiving. What strategies does he or she use to reduce stress? To what extent does the caregiver share caregiving burdens with family members and enlist the support of community organizations?

In Denmark, Sweden, and Japan, a government-sponsored home helper system eases the burden of parental care by making specially trained nonfamily caregivers available, based on older adults’ needs (Saito, Auestad, & Waerness, 2010). In the United States, in-home care by a nonfamily caregiver is too costly for most families; less than one-third of nonpaid family caregivers report receiving supplementary paid help from others (AARP, 2015). And unless they must, few people want to place their parents in formal care, such as nursing homes, which also are expensive. Applying What We Know on page 558 summarizes ways to relieve the stress of caring for an aging parent—at the individual, family, community, and societal levels. We will address additional care options, along with interventions for caregivers, in Chapter 17.

## Siblings

As Tim’s relationship with his sister reveals, siblings are ideally suited to provide social support. Nevertheless, a survey of a large sample of ethnically diverse Americans revealed that sibling contact and support decline from early to middle adulthood, rebounding only after age 70 for siblings living near each other (White, 2001). Decreased midlife contact is probably due to the demands of middle-aged adults’ diverse roles. However, most adult siblings report getting together or talking on the phone at least monthly (Antonucci, Akiyama, & Merline, 2002).

Despite reduced contact, many siblings feel closer in midlife, often in response to major life events (Stewart et al., 2001). Launching and marriage of children seem to prompt siblings to think more about each other. As Tim commented, “It helped our relationship when my sister’s children were out of the house and married. I’m sure she cared about me. I think she just didn’t have time!” And when parents die, adult children often realize that they have become the oldest generation and must look to each other to sustain family ties.

Not all sibling bonds improve, of course. Recollections of parental favoritism in childhood, and fathers’ current favoritism, are associated with negativity in adult sibling relationships (Gilligan et al., 2013; Suitor et al., 2009). The influence of mothers’ current favoritism is complex. In one study, middle-aged children expressed greater closeness to siblings whom they perceived their mother favored, and reduced closeness to siblings their mother disfavored (Gilligan, Suitor, & Nam, 2015). Perhaps adult children were drawn toward or away from certain siblings by the same traits that had affected their mothers. Or they might have attempted to improve their own status with their mothers

## Applying what we Know

### Relieving the Stress of Caring for an Aging Parent

STRATEGY	DESCRIPTION
Use effective coping strategies.	Use problem-centered coping to manage the parent's behavior and caregiving tasks. Delegate responsibilities to other family members, seek assistance from friends and neighbors, and recognize the parent's limits while calling on capacities the parent does have. Use emotion-centered coping to reinterpret the situation in a positive way, such as emphasizing the opportunity it offers for personal growth and for giving to parents in the last years of their lives. Avoid denial of anger, depression, and anxiety in response to the caregiving burden, which heightens stress.
Seek social support.	Confide in family members and friends about the stress of caregiving, seeking their encouragement and help. So far as possible, avoid quitting work to care for an ill parent; doing so is associated with social isolation and loss of financial resources.
Make use of community resources.	Contact community organizations to seek information and assistance, in the form of caregiver support groups, in-home respite help, home-delivered meals, transportation, and adult day care.
Press for workplace and public policies that relieve the emotional and financial burdens of caring for an aging parent.	Encourage your employer to provide benefits, such as flexible work hours and employment leave, for caregiving. Communicate with lawmakers and other citizens about the need for public policies to help pay for caregiving. Emphasize the need for improved health insurance plans that reduce the financial strain of caring for an aging parent on middle- and low-income families.

by bonding with favored siblings and avoiding disfavored ones. Large inequities in parental caregiving can also unleash sibling tensions (Silverstein & Giarrusso, 2010; Sutor et al., 2013). And when aging parents need care, sibling conflict worsens if perceptions of parental favoritism are present.

As in early adulthood, sister–sister relationships tend to be closer than sister–brother and brother–brother ties, a difference apparent in many industrialized nations (Cicirelli, 1995; Fowler, 2009). But a comparison of middle-aged men of the baby-boom generation with those of the preceding cohort revealed warmer, more expressive ties between baby-boom brothers (Bedford &

Avioli, 2006). A contributing factor may be baby boomers' more flexible gender-role attitudes.

In industrialized nations, sibling relationships are voluntary. In village societies, they are generally involuntary and basic to family functioning. For example, among Asian Pacific Islanders, family social life is organized around strong brother–sister attachments. A brother–sister pair is often treated as a unit in exchange marriages with another family. After marriage, brothers are expected to protect sisters, and sisters serve as spiritual mentors to brothers. Families not only include biological siblings but bestow on other relatives, such as cousins, the status of brother or sister, creating an unusually large network of life-long sibling support (Cicirelli, 1995). Cultural norms reduce sibling conflict, thereby ensuring family cooperation.

## Friendships

As family responsibilities declined in middle age, Devin found he had more time to spend with friends. On Friday afternoons, he met several male friends at a coffee house, and they chatted for a couple of hours. But most of Devin's friendships were couple-based—relationships he shared with Trisha. Compared with Devin, Trisha more often got together with friends on her own.

Middle-aged friendships reflect the same trends discussed in Chapter 14. At all ages, men's friendships are less intimate than women's. Men tend to talk about sports, politics, and business, whereas women focus on feelings and life's challenges. Women report a greater number of close friends and say they both receive from and provide their friends with more emotional support (Fiori & Denckla, 2015).

© GERRI ENGBERG/THE IMAGE WORKS

These middle-aged sisters express their mutual affection at a reunion. Even when they have only limited contact, siblings, especially sisters, often feel closer in midlife.

Because of their demanding everyday lives, many middle-aged adults welcome the ease of keeping in touch with friends through social media. Though falling short of young adults' use, connecting regularly with friends through Facebook and other social media sites has risen rapidly among U.S. middle-aged adults (see Figure 16.5) (Perrin, 2015). As in early adulthood, women tend to be more active users. And users have more offline close relationships, sometimes using Facebook to revive “dormant” friendships.

Still, for both sexes, number of friends declines from middle to late adulthood, probably because people become less willing to invest in nonfamily ties unless they are very rewarding. As selectivity of friendship increases, older adults try harder to get along with friends (Antonucci & Akiyama, 1995). Having chosen a friend, middle-aged people attach great value to the relationship and take extra steps to protect it.

### LOOK and LISTEN

Ask a middle-aged couple you know well to describe the number and quality of their friendships today compared with their friendships in early adulthood. Does their report match research findings? Explain.

By midlife, family relationships and friendships support different aspects of psychological well-being. Family ties protect against serious threats and losses, offering security within a long-term timeframe. In contrast, friendships serve as current sources of pleasure and satisfaction, with women benefiting somewhat

more than men (Levitt & Cici-Gokaltun, 2011). As middle-aged couples renew their sense of companionship, they may combine the best of family and friendship.

## Ask yourself

**CONNECT** Cite evidence that early family relationships affect middle-aged adults' bonds with adult children, aging parents, and siblings.

**APPLY** Raylene and her brother Walter live in the same city as their aging mother, Elsie. When Elsie could no longer live independently, Raylene took primary responsibility for her care. What factors probably contributed to Raylene's involvement in caregiving and Walter's lesser role?

**REFLECT** Ask one of your parents for his or her view of how the parent-child relationship changed as you transitioned to new adult roles, such as college student, career-entry worker, married partner, or parent. Do you agree?

## Vocational Life

**16.8** Discuss job satisfaction and career development in middle adulthood, with special attention to gender differences and experiences of ethnic minorities.

**16.9** Discuss career change and unemployment in middle adulthood.

**16.10** Discuss the importance of planning for retirement.

**FIGURE 16.5** Gains in use of social media sites by age group from 2005 to 2015. Repeated surveys of large representative samples of U.S. adults revealed that use of social media sites increased substantially for all age groups. Though not as avid users as young adults, most middle-aged adults use social media sites, primarily Facebook. (From A. Perrin, 2015, “Social Media Usage: 2005–2015.” Pew Research Center’s Internet & American Life Project, Washington, D.C., October 8, 2015, [www.pewinternet.org](http://www.pewinternet.org). Adapted by permission.)

Work continues to be a salient aspect of identity and self-esteem in middle adulthood. More so than in earlier or later years, people attempt to increase the personal meaning and self-direction of their vocational lives. At the same time, certain aspects of job performance improve. Middle-aged employees have lower rates of absenteeism, turnover, and accidents. They are also more effective workplace citizens—more often helping colleagues and trying to improve group performance and less often complaining about trivial issues. And because of their greater knowledge and experience, their work productivity typically equals or exceeds that of younger workers (Ng & Feldman, 2008). Consequently, an older employee ought to be as valuable as a younger employee, and possibly more so.

The large tide of baby boomers currently moving through midlife and (as we will see in Chapter 18) the desire of most to work longer than the previous generation means that the number of older workers will rise dramatically over the next few decades (Leonesio et al., 2012). Yet a favorable transition from adult worker to older worker is hindered by negative stereotypes of aging—incorrect assumptions of limited learning capacity, slower decision making, and resistance to change and supervision (Posthuma & Campion, 2009). Furthermore, gender discrimination continues to restrict the career attainments of many women. Let’s take a close look at middle-aged work life.

## Job Satisfaction

Job satisfaction has both psychological and economic significance. If people are dissatisfied at work, the consequences include absenteeism, turnover, grievances, and strikes, all of which are costly to employers.

Research shows that job satisfaction increases in midlife in diverse nations and at all occupational levels, from executives to hourly workers (see Figure 16.6). When different aspects of jobs are considered, intrinsic satisfaction—happiness with the work itself—shows a strong age-related gain (Barnes-Farrell & Matthews, 2007). Extrinsic satisfaction—contentment with supervision, pay, and promotions—changes very little.

But the age-related increase in job satisfaction is weaker for women than for men. More women take leaves from work, drop to part-time, or use flexible schedule arrangements to meet family obligations, deviating from the U.S. “ideal-worker” expectation of complete commitment to their job, through long work hours. In response, employers may penalize them—circumstances that lead them to feel unfairly treated (Kmec, O’Connor, & Schieman, 2014). Women’s reduced chances for advancement may also lessen contentment with work life. The midlife rise in job satisfaction is also weaker for blue-collar than for white-collar workers, perhaps because blue-collar workers have less control over their own work schedules and activities (Avolio & Sosik, 1999).

What explains the overall rise in job satisfaction during middle adulthood? An improved capacity to cope effectively with difficult situations and a broader time perspective probably contribute. “When I first started teaching, I complained about a lot

**FIGURE 16.6** Age-related gain in job satisfaction from early to middle adulthood. In this study of more than 2,000 university employees at all levels, from secretary to university president, job satisfaction dropped slightly in early adulthood as people encountered some discouraging experiences (see Chapter 14). In middle age, job satisfaction showed a steady rise. (From W. A. Hochwarter et al., 2001, “A Note on the Nonlinearity of the Age–Job-Satisfaction Relationship,” *Journal of Applied Social Psychology*, 31, p. 1232. Copyright © 2001, John Wiley and Sons. Reproduced with permission of Wiley Inc.)

of things,” remarked Devin. “From my current vantage point, I can tell a big problem from a trivial one.” Moving out of unrewarding work roles, as Trisha did when she moved from a large to a small law firm, where she felt appreciated, can also boost morale. Key characteristics that predict job well-being include involvement in decision making, reasonable workloads, and good physical working conditions. Older people may have greater access to jobs that are attractive in these ways. Furthermore, having fewer alternative positions into which they can move, older workers generally reduce their career aspirations (Warr, 2001, 2007). As the perceived gap between actual and possible achievements narrows, job involvement—importance of one’s work to self-esteem—increases.

Although emotional engagement with work is usually seen as psychologically healthy, it can also result in **burnout**—a condition in which long-term job stress leads to mental exhaustion, a sense of loss of personal control, and feelings of reduced accomplishment. Burnout occurs more often in the helping professions, including health care, human services, and teaching, which place high emotional demands on employees. Although people in interpersonally demanding jobs are as psychologically healthy as other people, sometimes a worker’s dedication exceeds his or her coping skills, especially in an unsupportive work environment (Schmidt, Neubach, & Heuer, 2007). Burnout is associated with excessive work assignments for available time and lack of encouragement and feedback from supervisors.

Burnout is a serious occupational hazard, linked to impaired attention and memory, severe depression, on-the-job injuries, physical illnesses, poor job performance, absenteeism, and turnover (Ahola & Hakanen, 2014; Sandström et al., 2005). To prevent burnout, employers can make sure workloads are reasonable, provide opportunities for workers to take time out from stressful situations, limit hours of stressful work, and offer social support. Interventions that augment employee control over schedule and supervisor support for family and personal life show promise for sustaining work engagement and effectiveness while preventing burnout (Kelly et al., 2014; Margolis, Matthews, & Lapierre, 2014; Moen et al., 2011). Improved employee health behaviors, including increased nightly sleep, and gains in work–family balance help explain these positive outcomes.

## Career Development

Recall from Chapter 15 that after her oldest child left home, Anya earned a college degree and entered the work force for the first time. After several years as a parish nurse, she felt a need for additional training to do her job better. Trisha appreciated her firm’s generous support of workshop and course attendance, which helped her keep abreast of new legal developments. And as college dean, Devin took a summer seminar on management effectiveness. As these experiences reveal, career development is vital throughout work life.

**Job Training.** Anya’s 35-year-old supervisor, Roy, was surprised when she asked for time off to upgrade her skills. “You’re

in your fifties,” he replied. “What’re you going to do with so much new information at this point in your life?”

Roy’s insensitive, narrow-minded response, though usually unspoken, is all too common among managers—even some who are older themselves! Research suggests that training and on-the-job career counseling are less available to older workers. And when career development activities are offered, older employees may be less likely to volunteer for them (Barnes-Farrell & Matthews, 2007; Cappelli & Novelli, 2010). What influences willingness to engage in job training and updating?

Personal characteristics are important: With age, growth needs give way somewhat to security needs. Consequently, learning and challenge may have less intrinsic value to many older workers. Perhaps for this reason, older employees depend more on co-worker and supervisor encouragement for vocational development (Claes & Heymans, 2008). Yet as we have seen, they are less likely to have supportive supervisors. Furthermore, negative stereotypes of aging reduce older workers’ self-efficacy, or confidence, that they can get better at their jobs (Maurer, Wrenn, & Weiss, 2003). Self-efficacy is a powerful predictor of employees’ efforts to renew and expand career-relevant skills.

Workplace characteristics matter, too. An employee given work that requires new learning must pursue that learning to complete the assignment. Unfortunately, older workers sometimes receive more routine tasks than younger workers. Therefore, some of their reduced motivation to engage in career-relevant learning may be due to the type of assignments they receive. In companies with a more favorable *age climate* (view of older workers), mature employees participate frequently in further education, and they also report greater self-efficacy, work commitment, and job satisfaction (Bowen, Noack, & Staudinger, 2011; MacDonald & Levy, 2016).

**Gender and Ethnicity: The Glass Ceiling.** In her thirties, Jewel became a company president by starting her own business. Having concluded that, as a woman, she had little chance of rising to a top executive position in a large corporation, she didn’t even try. Although women and ethnic minorities have gradually gained in access to managerial careers, they remain a long distance from gender and ethnic equality.

From career entry on, inequalities in promotion between men and women and between whites and blacks become more pronounced over time—findings still evident after education, work skills, and work productivity have been controlled (Barreto, Ryan, & Schmitt, 2009; Huffman, 2012). Women who are promoted usually get stuck in mid-level positions. When the most prestigious high-level management jobs are considered, white men are overwhelmingly advantaged: They account for 72 percent of chief executive officers at large corporations and 96 percent at Fortune 500 companies (U.S. Department of Labor, 2016a).

Women and ethnic minorities face a **glass ceiling**, or invisible barrier to advancement up the corporate ladder. Why is this so? Management is an art and skill that must be taught. Yet women and ethnic minorities have less access to mentors, role

BRENDAN SWIAŁOWSKI/AFP/GETTY IMAGES

Phebe Novakovic became CEO of General Dynamics at age 55. She is among a handful of women who have attained the top leadership position in a major corporation.

models, and informal networks that serve as training routes (Baumgartner & Schneider, 2010). And stereotyped doubts about women’s career commitment and ability to become strong managers (especially women with children) also contribute, leading supervisors to underrate their competence and not to recommend them for formal management training programs (Hoobler, Lemmon, & Wayne, 2011). Furthermore, challenging, high-risk, high-visibility assignments that require leadership and open the door to advancement, such as startup ventures, international experience, and troubleshooting, are less often granted to both women and minorities.

Finally, women who demonstrate qualities linked to leadership and advancement—assertiveness, confidence, forcefulness, and ambition—encounter prejudice because they deviate from traditional gender roles, even though they more often combine these traits with a democratic, collaborative style of leading than do men (Carli, 2015; Cheung & Halpern, 2010). To overcome this bias, women in line for top positions must demonstrate greater competence than their male counterparts. In an investigation of several hundred senior managers at a multinational financial services corporation, promoted female managers had earned higher performance ratings than promoted male managers (Lyness & Heilman, 2006). In contrast, no gender difference existed in performance of managers not selected for promotion.

Like Jewel, many women have dealt with the glass ceiling by going around it, leaving the corporate environment and going into business for themselves. Over the past two decades, startup businesses in the United States owned and operated by women grew at 1½ times the national average. And today, one-third of women-owned firms have ethnic minority owners. The large majority of women entrepreneurs are successful, meeting or exceeding their earnings goals (American Express Open, 2014). But when women and ethnic minorities leave the corporate world to further their careers, companies not only lose valuable talent but also fail to address the leadership needs of an increasingly diverse work force.

## Career Change at Midlife

Although most people remain in the same vocation through middle age, career change does occur, as with Elena's shift from journalism to teaching and creative writing. Recall that circumstances at home and at work motivated Elena's decision to pursue a new vocation. Like other career changers, she wanted a more satisfying life—a goal she attained by ending an unhappy marriage and initiating a long-awaited vocational move at the same time.

As noted earlier, midlife career changes are seldom radical; they typically involve leaving one line of work for a related one. Elena sought a more stimulating, involving job, a direction pursued by more middle-aged professional women than men (Mainiero & Sullivan, 2005). But other people move in the reverse direction—to careers that are more relaxing, free of painful decisions, and less demanding (Juntunen, Wegner, & Matthews, 2002). The decision to change is often difficult. The individual must weigh years invested in one set of skills, current income, and job security against present frustrations and hoped-for gains.

An extreme career shift, by contrast, usually signals a personal crisis (Young & Rodgers, 1997). In a study of professionals who abandoned their well-paid, prestigious positions for routine, poorly paid, semiskilled work, nonwork problems contributed to radical change. An eminent 55-year-old TV producer became a school bus driver, a New York banker a waiter in a ski resort (Sarason, 1977). Each was responding to feelings of personal meaninglessness—escaping from family conflict, difficult relationships with colleagues, and work that had become unsatisfying to a less burdensome life.

Among blue-collar workers—such as those employed in construction, manufacturing, mining, maintenance, or food-service work—midlife career shifts are seldom freely chosen. In one investigation, researchers followed a large sample of blue-collar men in their fifties over a seven-year period; all were employed

by Alcoa, the world's largest producer of aluminum. One-third had highly physically taxing jobs. Of the small minority who transitioned to less physically demanding work, an injury usually preceded the change (Modrek & Cullen, 2012). Transitioners appeared to change jobs to stay in the work force, rather than being forced to retire early because of their disability, at less than full pension benefits.

Yet opportunities to shift to less physically demanding work are usually limited. A strong predictor of middle-aged workers' eligibility for such jobs is education—at least a high school diploma (Blau & Goldstein, 2007). Less educated workers with a physical disability face greatly reduced chances of remaining in the labor force.

## Unemployment

As companies downsize, eliminating jobs, the majority of people affected are middle-aged and older. Although unemployment is difficult at any time, middle-aged adults show a sharper decline in physical and mental health than their younger counterparts. Those who perceive a company's layoff process as unfair and inconsiderate—for example, giving them little time to prepare—often experience the event as highly traumatic. Older job-seekers receive fewer job offers and remain jobless longer (McKee-Ryan et al., 2009; Wanberg et al., 2016). In addition, people over age 40 who must reestablish occupational security find themselves “off-time” in terms of the social clock. Consequently, job loss can disrupt major tasks of midlife, including generativity and reappraisal of life goals and accomplishments. Finally, having been more involved in and committed to an occupation, the older unemployed worker has also lost something of greater value.

People who lose their jobs in midlife, whether executives or blue-collar workers, seldom duplicate the status and pay of their previous positions. As they search, they encounter age discrimination and find that they are overqualified for many openings—experiences that weaken their motivation to continue searching. Those also facing financial difficulties are at risk for deepening depression and physical health declines over time (Gallo et al., 2006; Kanfer, Beier, & Ackerman, 2013). Counseling that focuses on financial planning, reducing feelings of humiliation due to the stigma of unemployment, and training in effective job search strategies, including social networking and use of social media, can help people implement effective problem-centered coping strategies in their search for alternative work roles.

## Planning for Retirement

One evening, Devin and Trisha met Anya and her husband, George, for dinner. Halfway through the meal, Devin inquired, “George, tell us what you and Anya are going to do about retirement. Are you planning to close down your business or work part-time? Do you think you'll stay here or move out of town?”

Three generations ago, the two couples would not have had this conversation. Because of government-sponsored retirement benefits (begun in the United States in 1935), retirement is no longer a privilege reserved for the wealthy. The federal

© JEFF MINTON PHOTOGRAPHY

In his mid-forties, after many years as a professor of ancient Greek philosophy, Abe Schoener transformed his passion for winemaking into a new career as a vintner. This radical shift prompted the breakup of his marriage but ultimately led to a more satisfying life.

## Applying what we Know

### Ingredients of Effective Retirement Planning

ISSUE	DESCRIPTION
Finances	Ideally, financial planning for retirement should start with the first paycheck; at a minimum, it should begin 10 to 15 years before retirement.
Fitness	Starting a fitness program in middle age is important because good health is crucial for well-being in retirement.
Role adjustment	Retirement is more challenging for people who strongly identify with their work role. Preparing for a radical role adjustment reduces stress.
Where to live	The pros and cons of moving should be considered carefully because where one lives affects access to health care, friends, family, recreation, entertainment, and part-time employment.
Leisure and volunteer activities	A retiree typically gains an additional 50 hours per week of free time. Careful planning of what to do with that time has a major impact on psychological well-being.
Health insurance	Finding out about government-sponsored health insurance options helps protect quality of life after retirement.
Legal affairs	The preretirement period is an excellent time to finalize a will and begin estate planning.

government pays Social Security to the majority of retired adults, and others are covered by employer-based private pension plans.

As the trend just noted suggests, the average age of retirement declined over the twentieth century, but over the past two decades, it has risen from age 57 to 62 in the United States. A similar rise has occurred in other Western nations, where average retirement age hovers between 60 and 63. Many U.S. baby boomers say they expect to delay retirement (Gallup, 2014; Kojola & Moen, 2016). But even with the negative impact of the economic recession of 2007 to 2009, most will need to work just a few extra years to be financially ready to retire (Munnell et al., 2012). For the healthy, active, long-lived baby-boom generation, up to one-fourth of their lives may lie ahead after they leave their jobs.

Retirement is a lengthy, complex process that begins as soon as the middle-aged person first thinks about it. Planning is important because retirement leads to a loss of two important work-related rewards—income and status—and to a change in many other aspects of life. Like other life transitions, retirement can be stressful. Clarifying goals for the future and acquiring financial-planning knowledge consistently predict better retirement savings, adjustment, and satisfaction (Hershey et al., 2007; Mauratore & Earl, 2015). Yet half or more of U.S. adults over age 50 have not engaged in any concrete retirement planning (Brucker & Leppel, 2013).

Applying What We Know above lists the variety of issues addressed in a typical retirement preparation program. Financial planning is especially vital in the United States where (unlike Western European nations) the federal government does not offer a pension system that guarantees an adequate standard of living (see page 65 in Chapter 2). Hence, U.S. retirees' income typically drops by 50 percent. But even midlifers who attend financial education programs often fail to look closely at their financial well-being and to make wise decisions (Keller & Lusardi, 2012). Many could benefit from an expert's financial analysis and counsel.

### LOOK and LISTEN

Contact the human resources division of a company or institution in your community, and inquire about the retirement planning services it offers. How comprehensive are those services, and what percentage of its recent retirees made use of them?

Retirement leads to ways of spending time that are largely guided by one's interests rather than one's obligations. Individuals who have not thought carefully about how to fill this time may find their sense of purpose in life seriously threatened. Planning for an active life has an even greater impact on happiness after retirement than financial planning (Mauratore & Earl, 2015). Participation in activities promotes many factors essential for psychological well-being, including a structured time schedule, social contact, and self-esteem. Carefully considering whether or not to relocate at retirement is related to an active life, since it affects access to health care, friends, family, recreation, entertainment, and part-time work.

Devin retired at age 62, George at age 66. Though several years younger, Trisha and Anya—like many married women—coordinated their retirements with those of their husbands. In contrast, Jewel—in good health but without an intimate partner to share her life—kept her consulting business going until age 75. Tim took early retirement and moved to be near Elena, where he devoted himself to public service—tutoring second graders in a public school, transporting inner-city children to museums, and coaching after-school and weekend youth sports. For Tim, retirement offered new opportunities to give generously to his community.

Unfortunately, less well-educated people with lower lifetime earnings are least likely to attend retirement preparation programs—yet they stand to benefit the most. And compared with men, women do less planning for retirement, instead relying on

their husband's preparations. This gender gap seems to be narrowing, however, as women increasingly contribute to family income (Adams & Rau, 2011; Wöhrman, Deller, & Wang, 2013). Employers must take extra steps to encourage lower-paid workers and women to participate in planning activities. In addition, enhancing retirement adjustment among the economically disadvantaged depends on access to better vocational training, jobs, and health care at early ages. Clearly, a lifetime of opportunities and experiences affects the transition to retirement. In Chapter 18, we will consider the decision to retire and retirement adjustment in greater detail.

## Ask yourself

**CONNECT** Supervisors sometimes assign more routine tasks to older workers, believing that they can no longer handle complex assignments. Cite evidence from this and the previous chapter indicating that this assumption is incorrect.

**APPLY** An executive wonders how his large corporation can foster advancement of women and ethnic minorities to upper management positions. What strategies would you recommend?

## Summary / chapter 16

### Erikson's Theory: Generativity versus Stagnation (p. 538)

#### 16.1 According to Erikson, how does personality change in middle age?

- Generativity expands as middle-aged adults face Erikson's psychological conflict of **generativity versus stagnation**. Personal desires and cultural demands jointly shape adults' generative activities.
- Highly generative people, who demonstrate workplace leadership, deep concern for others' welfare, and engagement in community and society, appear especially well-adjusted. Stagnation occurs when people become self-centered and self-indulgent in midlife.

### Other Theories of Psychosocial Development in Midlife (p. 541)

#### 16.2 Describe Levinson's and Vaillant's views of psychosocial development in middle adulthood, and discuss similarities and differences between men and women.

- According to Levinson, middle-aged adults confront four developmental tasks requiring them to reconcile opposing tendencies: young–old, destruction–creation, masculinity–femininity, and engagement–separateness.

- Middle-aged men show greater acceptance of “feminine” traits of nurturance and caring, while women are more open to “masculine” characteristics of autonomy and assertiveness. Men and successful career-oriented women may reduce their concern with achievement, but some women who have devoted themselves to child rearing or an unfulfilling job may pursue a long-desired ambition.
- Vaillant found that adults in their late fifties and sixties become guardians of their culture, “passing the torch” to later generations.

#### 16.3 Does the term midlife crisis reflect the typical experience of middle adulthood, and is midlife accurately characterized as a stage?

- Most midlifers make changes best described as “turning points.” Only a minority experience a **midlife crisis**—intense self-doubt and stress leading to drastic life alterations.
- Life regrets are associated with less favorable psychological well-being, but they can also prompt corrective action.
- Because major restructuring in midlife is rare, most experts do not view midlife as stagelike.

### Stability and Change in Self-Concept and Personality (p. 543)

#### 16.4 Describe changes in self-concept, personality, and gender identity in middle adulthood.

- Middle-aged individuals maintain self-esteem and stay motivated by revising their **possible selves**, which become fewer in number as well as more modest and concrete. Balanced possible selves, consisting of related hoped-for and feared outcomes, seem to enhance motivation to attain self-relevant goals.

- Midlife typically brings enhanced psychological well-being through greater self-acceptance, autonomy, and environmental mastery.
- Daily stressors plateau in early to mid-adulthood, and then decline as work and family responsibilities ease. Midlife gains in emotional stability and confidence in handling life's problems lead to increased effectiveness in coping with stressors. But some midlifers are overwhelmed by intense stress, as indicated by the rise in U.S. suicides during middle age.

MORSA IMAGES/GETTY IMAGES

- In earlier research, both men and women became more androgynous in middle adulthood, likely due to a combination of social roles and life conditions. This rise in androgyny seems to have spread to other age periods in response to cultural changes favoring gender equality.

#### 16.5 Discuss stability and change in the “big five” personality traits in adulthood.

- Among the “**big five**” **personality traits**, agreeableness and conscientiousness increase into middle age, while neuroticism declines, and extroversion and openness to experience do not change or decrease slightly. Although adults change in overall organization and integration of personality, they do so on a foundation of basic, enduring dispositions.

## Relationships at Midlife (p. 549)

### 16.6 Describe the middle adulthood phase of the family life cycle, including marriage, divorce, parent–child relationships, and grandparenthood.

- “Launching children and moving on” is the midlife phase of the family life cycle. Adults must adapt as their children launch–return–relaunch, marry, and produce grandchildren, and as their own parents age and die.

LORI ADAMSKI PEEK/WORKBOOK STOCK/GETTY IMAGES

- Marital satisfaction is a powerful predictor of midlife psychological well-being. Compared to younger people, middle-aged adults seem to adjust more easily to divorce. Marital breakup often severely reduces women’s standard of living, contributing to the **feminization of poverty**.
- Most middle-aged parents adjust well to launching adult children, especially if positive parent–child relationships are sustained, but adult children who are “off-time” in development can prompt parental strain. Low-SES parents are able to give less tangible and intangible support to their adult children, and they must divide it among more offspring. As children marry, middle-aged parents, especially mothers, often become **kinkeepers**.
- Grandparents’ relationships with grandchildren depend on proximity, number of grandchild sets, sex of grandparent and grandchild, and in-law relationships. In low-income families and in some ethnic groups, grandparents provide essential child-rearing assistance. When serious family problems exist, grandparents may become primary caregivers in **skipped-generation families**.

- Middle-aged adults reassess their relationships with aging parents, often becoming more appreciative. Mother–daughter relationships tend to be closer than other parent–child ties. The more positive the history of the parent–child tie and the greater the need for assistance, the more help exchanged.
- Middle-aged adults, often caught between caring for aging parents, assisting young-adult children and grandchildren, and meeting work and community responsibilities, are called the **sandwich generation**. The burden of caring for ill or frail parents falls most heavily on adult daughters, though the sex difference declines in later midlife age.
- Parental caregiving has emotional and health consequences, especially in cultures and subcultures where adult children feel a particularly strong obligation to provide care. Social support is highly effective in reducing caregiver stress and helping adult children derive benefits from caregiving.

### 16.7 Describe midlife sibling relationships and friendships.

- Sibling contact and support decline from early to middle adulthood, but many middle-aged siblings feel closer, often in response to major life events. Past and current parental favoritism influences the quality of sibling bonds.
- In midlife, friendships become fewer, more selective, and more deeply valued. Men continue to be less expressive with their friends than women, who have more close friendships.

## Vocational Life (p. 559)

### 16.8 Discuss job satisfaction and career development in middle adulthood, with special attention to gender differences and experiences of ethnic minorities.

- Vocational readjustments are common as middle-aged people seek to increase the personal meaning and self-direction of their work lives. Certain aspects of job performance improve. Job satisfaction increases at all occupational levels, more so for men than for women.

BRENDAN SMIALOWSKI/GETTY IMAGES

- **Burnout** is a serious occupational hazard, especially for those in helping professions. It can be prevented by ensuring reasonable workloads, limiting hours of stressful work, and providing workers with social support.
- Both personal and workplace characteristics influence older workers’ engagement in career development. In companies with a more favorable age climate, mature employees report greater self-efficacy, work commitment, and job satisfaction.

- Women and ethnic minorities face a **glass ceiling** because of limited access to management training and prejudice against women who demonstrate leadership qualities. Many women, including ethnic minorities, further their careers by leaving the corporate world, often to start their own businesses.

### 16.9 Discuss career change and unemployment in middle adulthood.

- Midlife career change typically involves leaving one line of work for a related one. Radical career change often signals a personal crisis. Among blue-collar workers, midlife career shifts are seldom freely chosen.
- Unemployment is especially difficult for middle-aged adults, who constitute the majority of laid-off workers. Counseling can help them find alternative jobs, but these rarely match their previous status and pay.

### 16.10 Discuss the importance of planning for retirement.

- Retirement brings major life changes, including loss of income and status and increased free time. Besides financial planning, preparing for an active retirement is vital, with a strong impact on happiness. Low-paid workers and women need extra encouragement to engage in retirement planning.

## Development in Middle Adulthood

YELLOW DOG/CULTURA/GETTY IMAGES

### 40–50 YEARS

#### Physical

- Accommodative ability of the lens of the eye, ability to see in dim light, and color discrimination decline; sensitivity to glare increases. (508–509)
- Hearing loss at high frequencies occurs, and ability to distinguish sounds in close succession recedes. (509)
- Hair grays and thins. (508)
- Lines on the face become more pronounced; skin loses elasticity and begins to sag. (509–510)
- Weight gain continues, accompanied by a rise in fatty deposits in the torso, while fat beneath the skin declines. (510)
- Loss of lean body mass (muscle and bone) occurs. (510)

JEFF GREENBERG/PHOTODEDIT

- In women, production of estrogen drops, leading to shortening and irregularity of the menstrual cycle. (510)

- In men, quantity of semen and sperm declines. (513)
- Intensity of sexual response declines, but frequency of sexual activity drops only modestly. (515)
- Rates of cancer and cardiovascular disease increase. (516–519)

#### Cognitive

- Consciousness of aging increases. (508, 541)
- Crystallized intelligence increases; fluid intelligence declines. (525)

JETTY PRODUCTIONS/GETTY IMAGES

- Speed of processing declines, but adults can compensate through experience and practice. (527–528)
- Executive function—working memory capacity, inhibition, and flexible shifting of attention—declines, but adults can compensate through experience and practice. (528–529)
- Recall of studied information declines, in part because of reduced use of memory strategies. (529)
- Retrieving information from long-term memory becomes more difficult. (529)
- Semantic memory (general knowledge base), procedural memory (“how-to” knowledge), memory related to one’s occupation, and metacognitive knowledge remain unchanged or may increase. (529)

COMSTOCK/GETTY IMAGES

- Practical problem solving and expertise increase. (530)
- Creativity may become more deliberately thoughtful, emphasize integrating ideas, and shift from self-expression to more altruistic goals. (530–531)

© SPENCER GRANT/ALAMY

Note: Numbers in parentheses indicate the page or pages on which each milestone is discussed.

## Emotional/Social

- Generativity increases. (538–539)

- Focus shifts toward personally meaningful living. (541)
- Possible selves become fewer in number, more modest and concrete, and less far-off in realization. (544)
- Self-acceptance, autonomy, and environmental mastery increase. (544–545)
- Strategies for coping with stressors become more effective. (545)
- May become more androgynous in gender identity, with “masculine” traits increasing in women, “feminine” traits in men. (541, 546–548)
- Agreeableness and conscientiousness increase, while neuroticism declines. (548)
- May launch children. (551)
- May become a kinkeeper, especially if a mother. (552)
- May become a parent-in-law and a grandparent. (552–553)
- Becomes more appreciative of parents’ strengths and generosity; quality of relationships with parents increases. (554–555)
- May care for a parent with a disability or chronic illness. (555–557)
- Siblings may feel closer. (557–558)

- Number of friends generally declines. (559)
- Intrinsic job satisfaction—happiness with one’s work—typically increases. (560)

## 50–65 YEARS

### Physical

- Lens of the eye loses its capacity to adjust to objects at varying distances entirely. (508)
- Hearing loss gradually extends to all frequencies but remains greatest for high frequencies. (509)
- Skin continues to wrinkle and sag, “age spots” increase, and blood vessels in the skin become more visible. (510)
- In women, menopause occurs; as estrogen declines further, genitals are less easily stimulated, and the vagina lubricates more slowly during arousal. (510–512)
- In men, inability to attain an erection when desired becomes more common. (513)
- Loss of bone mass continues; rates of osteoporosis rise. (510, 519)

- Collapse of disks in the spinal column causes height to drop by as much as 1 inch. (510)
- Rates of cancer and cardiovascular disease continue to increase. (515–519)

### Cognitive

- Cognitive changes previously listed continue.

## Emotional/Social

- Emotional and social changes previously listed continue.

- Emotional support and practical assistance of aging parents increase. (555)

- May retire. (562–564)

DANIEL BEREHUIAK/THE NEW YORK TIMES/REDUX

## Physical and Cognitive Development in Late Adulthood

Cultures around the world connect age with wisdom. In most societies, leadership positions are typically held by older adults, whose life experience enhances their ability to solve human problems. Here, Liberian president and Nobel Peace laureate Ellen Johnson Sirleaf meets with the family of a teenage civilian who was fatally shot while protesting an Ebola quarantine.

At age 67, Walt gave up his photography business and looked forward to more spare time with 64-year-old Ruth, who retired from her position as a social worker at the same time. For Walt and Ruth, this culminating period of life was filled with volunteer work, golfing three times a week, and joint vacations with Walt's older brother Dick and his wife, Goldie. Walt also took up activities he had always loved but had little time to pursue—writing poems and short stories, attending theater performances, enrolling in a class on world politics, and cultivating a garden that became the envy of the neighborhood. Ruth read voraciously and served on the board of directors of an adoption agency.

Over the next 20 years, Walt and Ruth amazed nearly everyone who met them with their energy and vitality. Their warmth and concern for others led extended family and friends to seek them out. On weekends, their home was alive with visitors.

Then, in their early eighties, the couple's lives changed profoundly. Walt had surgery to treat a cancerous prostate gland and within three months was hospitalized again after a heart attack. He lingered for six weeks and then died. Ruth's grieving was interrupted by the need to care for her sister Ida. Alert and spry at age 78, Ida declined mentally in her seventy-ninth year, despite otherwise excellent physical health. Meanwhile, Ruth's arthritis worsened, and her vision and hearing weakened.

As Ruth turned 85, certain activities had become difficult—but not impossible. “It just takes a little adjustment!” Ruth exclaimed in her usual upbeat manner. Reading was harder, so she downloaded audiobooks to her smartphone. Her gait was slower and her eyesight less reliable, making her hesitant to go out alone. At dinner in a noisy restaurant with her daughter and family, Ruth felt overwhelmed and participated little in the fast-moving conversation. But in one-to-one interactions in a calm environment, she showed the same intelligence, wit, and astute insights that she had displayed all her life.

Late adulthood stretches from age 65 to the end of the lifespan. Unfortunately, popular images fail to capture the quality of these final decades. Instead, many myths prevail—that older people have entered a period of deterioration and dependency, that they are no longer able to learn, and that their families isolate them in nursing homes.

As we trace physical and cognitive development in late adulthood, we will see that the balance of gains and declines shifts as death approaches. But in industrialized nations, the typical 65-year-old can anticipate nearly two healthy, rewarding decades before this shift affects everyday life. And as Ruth illustrates, even after older adults become frail, many find ways to surmount physical and cognitive challenges.

Late adulthood is best viewed as an extension of earlier periods, not a break with them. As long as social and cultural contexts give older adults support, respect, and purpose in life, these years are a time of continued potential. ●

## PHYSICAL DEVELOPMENT

Do you know older adults who “seem young” or “seem old” for their age? In using these descriptors, we acknowledge that chronological age is an imperfect indicator of **functional age**, or actual competence and performance. Because people age biologically at different rates, some 80-year-olds appear younger than many 65-year-olds. Also, recall from Chapter 13 that within each person, change differs across parts of the body. For example, Ruth became infirm physically but remained active mentally, whereas Ida, though physically fit for her age, found it hard to converse with others, keep appointments, or complete familiar tasks.

So much variation exists between and within individuals that researchers have not yet identified any single biological measure that predicts the overall rate at which a person will age. But we do have estimates of how much longer older adults can expect to live, and our knowledge of factors affecting longevity in late adulthood has increased rapidly.

### Life Expectancy

**17.1** Distinguish between chronological age and functional age, and discuss changes in life expectancy since the beginning of the twentieth century.

Dramatic gains in **average life expectancy**—the number of years that an individual born in a particular year can expect to live, starting at any age—provide powerful support for the multiplicity of factors considered in previous chapters that slow biological aging, including improved nutrition, medical treatment, sanitation, and safety. Recall from Chapter 1 that in 1900, life expectancy was just under 50 years; in the United States today, it is 78.8—76 for U.S. men and 81 for women. A major factor in this extraordinary gain is a steady decline in infant mortality (see Chapter 3), but death rates among adults have decreased as well. For example, heart disease, the leading cause of overall adult death in the United States, has dropped by nearly 70 percent in the past four decades, due to declines in risk factors (such as high blood pressure and cigarette smoking) and, mostly, advances in medical treatment (Wilmot et al., 2016).

### Variations in Life Expectancy

Consistent group differences in life expectancy underscore the joint contributions of heredity and environment to biological aging. In countries around the globe, women outlive men, by an average of five years (Rochelle et al., 2015). This life expectancy advantage characterizes females of most species. The protective value of females’ extra X chromosome (see Chapter 2), along with their reduced risk taking and physical aggression (Chapters 6 and 8), are believed to be responsible. Yet since the 1990s, the gender gap in life expectancy has narrowed in industrialized

© PA IMAGES/ALAMY

People age biologically at different rates, making them look and feel younger or older than their agemates. Although these World War II veterans are the same age, the one on the left appears older than the one on the right.

nations (Deeg, 2016). Because men are at higher risk for disease and early death, they reap somewhat larger generational gains from positive lifestyle changes and new medical discoveries.

Life expectancy varies substantially with SES. As education and income increase, so does length of life (Chetty et al., 2016; Whitfield, Thorpe, & Szanton, 2011). In the United States, the gap in life expectancy at birth between the wealthiest and the poorest individuals is 14½ years for men and 10 years for women. SES also accounts for the 2- to 3-year advantage in life expectancy for European-American over African-American adults age 65 and older (Centers for Disease Control and Prevention, 2016b). As noted in Chapter 13, stressful life events, wide-ranging unhealthy behaviors, jobs with health risks, and weak social supports are associated with low SES.

EPA EUROPEAN PRESS PHOTO AGENCY B.V./ALAMY

In a Japanese seaside city, a spry aging couple practice their local tradition of net fishing. Japan’s low rates of obesity and heart disease and favorable health-care policies contribute to its worldwide leading status in healthy life expectancy.

Length of life—and, even more important, *quality of life* in old age—can be predicted by a country’s health care, housing, and social services, along with lifestyle factors. When researchers estimate **average healthy life expectancy**, the number of years a person born in a particular year can expect to live in full health, without disease or injury, Japan ranks first, with the United States falling below the overwhelming majority of industrialized nations (see Figure 17.1). Japan’s leading status in this overall measure of population health has been attributed to its low rates of obesity and heart disease (linked to its low-fat diet) along with its favorable health-care policies. Because the United States falls short in these respects, Americans spend somewhat more time disabled and die earlier than older adults in most other developed countries.

**FIGURE 17.1** Average healthy life expectancy at birth in 30 nations, ranked on measures for women. Japan ranks first, the United States a disappointing thirtieth. In each nation, women’s healthy life expectancy is about 2 to 3 years longer than men’s. (From Salomon et al., 2012.)

In developing nations with widespread poverty, malnutrition, disease, and armed conflict, average life expectancy hovers around 55 years. And healthy life expectancy is reduced by three to four decades compared with the industrialized world—for example, for males, 69 years in Japan, 67 years in Sweden, 65 years in the United States, but only 48 in Afghanistan, 47 in Sierra Leone, and 28 in Haiti, where overall health recently declined because of the 2010 catastrophic earthquake (Salomon et al., 2012).

## Life Expectancy in Late Adulthood

Although poverty-stricken groups lag behind the economically advantaged, the proportion of older adults has risen dramatically in the industrialized world. From 1900 to 2014, people age 65 and older increased from 4 percent to 15 percent of the U.S. population. Because of aging baby boomers, older adults are projected to rise to 20 percent by 2030. Among older Americans, the fastest-growing segment is the 85-and-older group, which has increased by 30 percent during the past decade and currently makes up nearly 2 percent of the U.S. population. By 2050, they are expected to swell to more than double their current number (U.S. Department of Health and Human Services, 2015e).

Americans reaching age 65 in the early twenty-first century can look forward, on average, to 19 more years of life. As at earlier ages, life expectancy is greater for older women than for men. Today, the 65- to 69-year age group includes 114 women for every 100 men; for people age 85 and older, this number climbs to 195 (U.S. Census Bureau, 2016c). Similar discrepancies exist throughout the world, with the exception of a few developing countries where death rates of women during childbirth are high or women experience severe discrimination and deprivation.

Although women outnumber men by a greater margin at older ages, women’s advantage in life expectancy shrinks with age—in the United States, from 3 years at age 65 to 1 year at age 85. Over age 100, the gender difference disappears (Arias, 2015). Similarly, differences in rates of chronic illness and in life expectancy between European Americans and African Americans lessen with age. After age 80, a *life expectancy crossover* occurs—surviving African Americans live longer than members of the white majority (Masters, 2012; Roth et al., 2016; Sautter et al., 2012). Researchers speculate that among men and economically disadvantaged African Americans, only the biologically sturdiest survive into very old age.

Throughout this book, we have seen that genetic and environmental factors jointly affect aging. With respect to heredity, identical twins typically die within 3 years of each other, whereas fraternal twins of the same sex differ by more than 6 years. Also, longevity runs in families. When both parents survive to age 70 or older, the chances that their children will live to 90 or 100 are double that of the general population (Cevenini et al., 2008; Hayflick, 1994; Mitchell et al., 2001). At the same time, evidence from twin studies suggests that once people pass 75 to 80 years, the contribution of heredity to length of life decreases in favor of

## Biology and Environment

### What Can We Learn About Aging from Centenarians?

Jeanne Louise Calment, listed in *Guinness World Records* as the longest-lived person whose age could be documented, was born in Arles, France, in 1875 and died there in 1997, at age 122. Heredity undoubtedly contributed to her longevity: Her father lived to age 94, her mother to 86. Her family was middle-SES, and in her twenties, she married a prosperous merchant (Robine & Allard, 1999). As a young woman, she was healthy and energetic; she bicycled, swam, roller-skated, played tennis, and ran up the steps of the cathedral to attend daily Mass.

Jeanne attributed her longevity to a diet rich in olive oil and an occasional glass of port wine. Others credit her agreeable disposition and resistance to stress. “If you can’t do anything about it,” she once said, “don’t worry about it.” Jeanne took up fencing at age 85 and rode a bicycle until 100. Shortly thereafter, she moved into assisted living (see pages 593–594), where she blossomed, becoming a celebrity because of both her age and her charming personality. Alert and quick-witted until her final year, she recommended laughter as the best recipe for long life. Asked once

about the effects of aging, she quipped, “I’ve only one wrinkle, and I am sitting on it.”

The past 25 years have seen a nearly five-fold increase in the world’s centenarian population, with women outnumbering men by 5 to 1. Currently, U.S. centenarians, though still rare (a fraction of 1 percent of the population), number about 72,000 (Stepler, 2016). The proportion of centenarians in the United States is smaller than in most other developed nations.

In a study of 96 U.S. centenarians, one-fourth reached age 100 with no major chronic disease, nearly as many had no physical disabilities, and 55 percent were free of cognitive impairments (Alishaire, Beltrán-Sánchez, & Crimmins, 2015). They were generally healthier than a comparison group of very old adults who died before their hundredth birthday.

These robust centenarians—leading active, autonomous lives—are of special interest because they represent the ultimate potential of the human species. What are they like? Results of several longitudinal studies reveal that they are diverse in years of education

PASCAL PARROT/SYGMA/SYGMA VIA GETTY IMAGE

Jeanne Louise Calment, shown here at age 121, took up fencing at age 85, rode a bicycle until age 100, and maintained a quick wit until her final year. The longest-lived person on record, she died at age 122.

(none to postgraduate), economic well-being (very poor to very rich), and ethnicity. At the same time, their physical condition and life stories reveal common threads.

environmental factors—a healthy diet; normal body weight; regular exercise; little or no tobacco, alcohol, and drug use; an optimistic outlook; low psychological stress; and social support (Yates et al., 2008; Zaretsky, 2003). As the Biology and Environment box above reveals, the study of centenarians—people who cross the 100-year mark—offers special insights into how biological, psychological, and social influences work together to promote a long, satisfying life.

### Maximum Lifespan

Finally, perhaps you are wondering: For humans, what is the **maximum lifespan**, or species-specific biological limit to length of life (in years), corresponding to the age at which the oldest known individual died? As the Biology and Environment box indicates, the oldest verified age is 122 years.

Does this figure actually reflect the upper bound of human longevity, or can it be extended? Some scientists believe that 122 years is close to the maximum, and 85 to 90 years is as much as most humans can expect. They point out that gains in average

life expectancy are largely the result of reducing health risks in the first 20 or 30 years—especially, the harmful behavioral and environmental conditions linked to poverty, limited education, and weak access to health care (Olshansky, 2011). For people age 65 and older, life expectancy has increased very little—only about 1½ years—over the past decade and a half. And although the number of centenarians is rising (see the Biology and Environment box), the odds of becoming a centenarian have been extremely low throughout human history and remain so today—in the U.S. population, just 5 for every 10,000 people, with most centenarians dying by age 103 (Arias, 2015). Nevertheless, other researchers remain convinced that we can add to human maximum lifespan.

This controversy raises another issue: *Should* maximum lifespan be increased as far as possible? Many people respond that the important goal is not just quantity of life, but quality—doing everything possible to extend healthy life expectancy. Most experts agree that only after reducing the high rates of preventable illness and disability among low-SES individuals and wiping out age-related diseases should we invest in lengthening the maximum lifespan.

## Health

Centenarians usually have grandparents, parents, and siblings who reached very old age, indicating a genetically based survival advantage. Likewise, their children, who are typically in their seventies and eighties, display fewer physical and cognitive impairments compared with older adults of similar age (Cosentino et al., 2013; Perls et al., 2002). Some centenarians share with siblings a segment of identical DNA on the fourth chromosome, suggesting that a certain gene, or several genes, may increase the likelihood of exceptionally long life (Perls & Terry, 2003).

Robust centenarians have a low incidence of genes associated with immune-deficiency disorders, cancer, and Alzheimer's disease. Consistent with these findings, they usually have efficiently functioning immune systems, and after-death examinations reveal few brain abnormalities (Silver & Perls, 2000). Other robust centenarians function well despite underlying chronic disease—typically atherosclerosis, other cardiovascular problems, and brain pathology (Berzlanovich et al., 2005; Evert et al., 2003). Compared with the general population, about four times as many centenarian women gave birth to healthy children after age 40 (Perls et al., 2000).

Late childbearing may indicate that the body, including the reproductive system, is aging slowly.

As a group, robust centenarians are of average or slender build and practice moderation in eating. Many have most or all of their own teeth—another sign of unusual physical health. The large majority report having never smoked, engaging in no more than moderate wine consumption, and sustaining a lifelong pattern of physical activity past age 100 (Hagberg & Samuelson, 2008; Kropf & Pugh, 1995).

## Personality

In personality, these very senior citizens appear highly optimistic (Jopp & Rott, 2006). In a study in which robust centenarians retook personality tests after 18 months, they reported more fatigue and depression, perhaps in response to increased frailty at the very end of their lives. But they also scored higher in tough-mindedness, independence, emotional security, and openness to experience—traits that may be vital for surviving beyond 100 (Martin, Long, & Poon, 2002). An important contributor to their favorable mental health and longevity is social support, especially close family bonds and a long and happy

marriage (Margrett et al., 2011). An unusually large percentage of centenarian men—about one-fourth—are still married.

## Activities

Robust centenarians have a history of community involvement—working for just causes that are central to their growth and happiness. Their past and current activities often include stimulating work, leisure pursuits, and learning, which may help sustain their good cognition and life satisfaction (Antonini et al., 2008; Weiss-Numeroff, 2013). Writing letters, poems, plays, and memoirs; making speeches; teaching music lessons and Sunday school; nursing the sick; chopping wood; selling merchandise, bonds, and insurance; painting; practicing medicine; and preaching sermons are among robust centenarians' varied involvements. In several cases, illiterate centenarians learned to read and write.

In sum, robust centenarians illustrate typical development at its best. These independent, mentally alert, happy 100-year-olds reveal how a healthy lifestyle, personal resourcefulness, and close ties to family and community can build on biological strengths, thereby pushing the limits of an active, fulfilling life.

## Physical Changes

**17.2** Describe physical declines of late adulthood, and changes in the nervous and sensory systems.

**17.3** Describe cardiovascular, respiratory, and immune system changes and sleep difficulties in late adulthood.

**17.4** Describe changes in physical appearance and mobility in late adulthood, along with effective adaptations to these changes.

The programmed effects of specific genes and the random cellular events believed to underlie biological aging (see Chapter 13) make physical declines more apparent in late adulthood. The majority of people age 65 and older are capable of living active, independent lives, but with age, growing numbers need assistance. After age 75, about 9 percent of Americans have difficulty carrying out **activities of daily living (ADLs)**—basic self-care tasks required to live on one's own, such as bathing, dressing, getting in and out of bed or a chair, or eating. And about 17 per-

cent cannot carry out **instrumental activities of daily living (IADLs)**—tasks necessary to conduct the business of daily life and also requiring some cognitive competence, such as telephoning, shopping, food preparation, housekeeping, and paying bills. The proportion of older adults with these limitations rises sharply with age (U.S. Department of Health and Human Services, 2015d). Nevertheless, most body structures can last into our eighties and beyond, if we take good care of them. For an overview of the physical changes we are about to discuss, return to Table 13.1 on page 441.

## Nervous System

On a routine office visit, 80-year-old Ruth's doctor asked her how she was getting along. "I think I might be losing my mind," Ruth replied anxiously. "Yesterday, I forgot the name of the family who just moved in next door. And the day before, I had trouble finding the right words to explain to a delivery service how to get to my house."

“Ruth, everyone forgets those sorts of things from time to time,” Dr. Wiley reassured her. “When we were young and had a memory lapse, we reprimanded ourselves for being scatter-brained and thought no more about it. Now, when we do the same thing, we attribute it to having ‘a senior moment,’ and we worry.”

Ruth also wondered why extremes of hot and cold weather felt more uncomfortable than in earlier years. And she needed more time to coordinate a series of movements and had become less sure of her balance.

Aging of the central nervous system affects a wide range of complex activities. Although brain weight declines throughout adulthood, brain-imaging research and after-death autopsies reveal that the loss becomes greater starting in the fifties and amounts to as much as 5 to 10 percent by age 80, due to withering of the myelin coating on neural fibers, loss of synaptic connections, death of neurons, and enlargement of ventricles (spaces) within the brain (Fiocco, Peck, & Mallya, 2016; Rodrigue & Kennedy, 2011).

Neuron loss occurs throughout the cerebral cortex but at different rates among different regions and often inconsistently within parts of those regions. In longitudinal studies, the frontal lobes, especially the prefrontal cortex (responsible for executive function and strategic thinking), and the corpus callosum (which connects the two cortical hemispheres), tended to show greater shrinkage than the parietal, temporal, and occipital lobes (see page 120 in Chapter 4 for a visual image of these regions) (Fabiani, 2012; Lockhart & DeCarli, 2014). The cerebellum (which controls balance and coordination and supports cognitive processes) and the hippocampus (involved in memory and spatial understanding) also lose neurons (Fiocco, Peck, & Mallya, 2016). And EEG measures reveal gradual slowing and reduced intensity of brain waves—signs of diminished efficiency of the central nervous system (Kramer, Fabiani, & Colcombe, 2006).

But brain-imaging research reveals wide individual differences in the extent of these losses, which are moderately associated with declines in cognitive functioning (Ritchie et al., 2015). And the brain can overcome some decline. In several studies, growth of neural fibers in the brains of older adults unaffected by illness took place at the same rate as in middle-aged people. Aging neurons established new synapses after other neurons had degenerated (Flood & Coleman, 1988). Furthermore, the aging cerebral cortex can, to a limited degree, generate new neurons (Snyder & Cameron, 2012). And fMRI evidence reveals that compared with younger adults, older people who do well on memory and other cognitive tasks show more widely distributed activity across areas of the cerebral cortex, particularly in the prefrontal cortex and in regions mirroring typically active sites but located in the opposite hemisphere (Fabiani, 2012; Reuter-Lorenz & Cappell, 2008). This suggests that one way older adults compensate for neuron loss is to call on additional brain regions to support cognitive processing.

The autonomic nervous system, involved in many life-support functions, also performs less well, placing older adults at risk during heat waves and cold spells. For example, Ruth’s reduced tolerance for hot weather was due to decreased sweating.

And her body found it harder to raise its core temperature during cold exposure. However, among physically fit older people who are free of disease, these declines are mild (Blatteis, 2012). The autonomic nervous system also releases higher levels of stress hormones into the bloodstream than it did earlier, perhaps to arouse body tissues that have become less responsive to these hormones over the years (Whitbourne, 2002). As we will see, this change may contribute to decreased immunity and to sleep problems.

## Sensory Systems

Changes in sensory functioning become increasingly noticeable in late life. Older adults see and hear less well, and their taste, smell, and touch sensitivity also decline. As Figure 17.2 shows, in late life, hearing impairments are more common than visual impairments. Extending trends in middle adulthood, more women than men report being visually impaired, more men than women hearing impaired.

**Vision.** In Chapter 15 (see pages 508–509), we noted that structural changes in the eye make it harder to focus on nearby objects, see in dim light, and perceive color. In late adulthood, vision diminishes further. The cornea (clear covering of the eye) becomes more translucent and scatters light, which blurs images and increases sensitivity to glare. The lens continues to yellow, leading to further impairment in color discrimination. The number of individuals with **cataracts**—cloudy areas in the lens, resulting in foggy vision and (without surgery) eventual blindness—increases tenfold from middle to late adulthood, affecting 25

**FIGURE 17.2** Rates of visual and hearing impairments among U.S. men and women by age. Among a large, nationally representative sample, those reporting that they had trouble seeing, even when wearing glasses or contact lenses, were judged visually impaired; those reporting “a lot of trouble” hearing were judged hearing impaired. Women report more visual impairments; men report more hearing impairments, a gap that widens considerably in late adulthood. In late life, hearing impairments become more common than visual impairments. (Based on U.S. Census Bureau, 2014.)

percent of people in their seventies and 50 percent of those in their eighties (Owsley, 2011; Sørensen, White, & Ramchandran, 2016). Besides biological aging, heredity, sun exposure, cigarette smoking, alcohol consumption, and certain diseases (such as hypertension and diabetes) increase the risk of cataracts (Thompson & Lakhani, 2015). Fortunately, removal of the lens and replacement with an artificial lens implant is highly successful in restoring vision.

Impaired eyesight in late adulthood largely results from a reduction in light reaching the retina (caused by yellowing of the lens, shrinking of the pupil, and clouding of the vitreous) and from cell loss in the retina and optic nerve (refer again to Chapter 15). Dark adaptation—moving from a brightly lit to a dim environment, such as a movie theater—becomes harder. A decline in binocular vision (the brain’s ability to combine images received from both eyes) makes depth perception less reliable. And visual acuity (fineness of discrimination) worsens, dropping sharply after age 70 (Owsley, 2011).

When light-sensitive cells in the macula, or central region of the retina, break down, older adults may develop **macular degeneration**, in which central vision blurs and gradually is lost. Macular degeneration is the leading cause of blindness among older adults. About 10 percent of 65- to 74-year-olds, and 30 percent of 75- to 85-year-olds, have symptoms. If diagnosed early, macular degeneration can sometimes be treated with laser therapy. As with cataracts, heredity (including several identified genes) increases risk, especially when combined with cigarette smoking or obesity (Schwartz et al., 2016; Wysong, Lee, & Sloan, 2009). Atherosclerosis also contributes by constricting blood flow to the retina. Protective factors include regular, brisk physical activity and a diet emphasizing fish high in omega-3 fatty acids, which promote cardiovascular health, and fruits and vegetables high in vitamins A, C, E, and carotenoids (yellow and red plant pigments), which help shield cells in the macula from toxic levels of free radicals (Broadhead et al., 2015).

Visual difficulties have a profound impact on older people’s self-confidence and everyday behavior. As she approached age 80, Ruth gave up driving, and she worried about Walt, who found it hard to shift focus between the road and the dashboard or to make out pedestrians at dusk and at night. On foot, problems with depth perception and dark adaptation increase older adults’ chances of stumbling.

When vision loss is extensive, it can affect leisure pursuits and be very isolating. Because of her poor vision, Ruth could no longer enjoy museums, movies, playing bridge, or working crossword puzzles, and she depended on others for help with housekeeping and shopping. But even among people age 85 and older, only 30 percent experience visual impairment severe enough to interfere with daily living (U.S. Census Bureau, 2014). For many, however, reduced vision goes undetected. Treatment is vital for sustaining quality of life.

**Hearing.** “Mom, I’d like you to meet Joe’s cousin Leona,” said Ruth’s daughter Sybil at a Thanksgiving gathering. But in the clamor of boisterous children, television sounds, and nearby

conversations, 85-year-old Ruth didn’t catch Leona’s name or her relationship to Sybil’s husband, Joe.

“Tell me your name again?” Ruth asked, adding, “Let’s go into the other room, where it’s quieter, so we can speak a bit.”

Reduced blood supply and natural cell death in the inner ear and auditory cortex, discussed in Chapter 15, along with stiffening of membranes (such as the eardrum), cause hearing to decline in late adulthood. Decrements are greatest at high frequencies, although detection of soft sounds diminishes throughout the frequency range (see page 509). In addition, responsiveness to startling noises lessens, and discriminating complex tone patterns becomes harder (Wettstein & Wahl, 2016).

Although hearing loss has less impact on self-care than vision loss, it affects safety and enjoyment of life. In the din of city traffic, 80-year-old Ruth didn’t always correctly interpret warnings, whether spoken (“Watch it, don’t step out yet”) or non-spoken (the beep of a horn). And when she turned up the radio or television volume, she sometimes missed the ring of the telephone or a knock at the door.

As hearing declines, older people report lower self-efficacy, more loneliness and depressive symptoms, and a smaller social network than their normally hearing peers (Kramer et al., 2002; Mikkola et al., 2015). Of all hearing difficulties, the age-related decline in speech perception has the greatest impact on life satisfaction. After age 70, ability to detect the content and emotionally expressive features of conversation declines, especially in noisy settings (Gosselin & Gagne, 2011).

Although Ruth used problem-centered coping to increase her chances of hearing conversation, she wasn’t always successful. At the family’s Thanksgiving reunion, fewer relatives took time to talk with Ruth, and she felt some pangs of loneliness. And sometimes people were inconsiderate. On a dinner outing, when Ruth asked Joe to repeat himself, he turned to Sybil and said loudly, “Be honest, Syb, Ruth’s going deaf, isn’t she?” Because aging adults with hearing loss frequently misunderstand verbal

Declines in hearing, especially the ability to perceive human speech, greatly reduce older adults’ enjoyment of life. Availability of assistive listening devices can help ensure that this couple gets the most out of a movie-going experience.

communication, others may conclude they are mentally impaired. Those with hearing loss, as well as those who are visually impaired, do obtain lower scores on tests of executive function and memory (Li & Bruce, 2016). The effort they must devote to perceiving information likely detracts from other cognitive processes needed to perform the tasks.

Yet an investigation that followed several thousand older people for up to 15 years revealed that the presence of hearing or visual impairments did not predict cognitive declines, once other factors linked to cognitive functioning (such as age, educational attainment, and chronic illnesses) were controlled (Hong et al., 2016). Assuming that older adults who hear or see poorly are mentally deficient is a mistaken, negative stereotype of aging.

Most older people do not suffer from hearing loss great enough to disrupt their daily lives until after age 85. For those who do, compensating with a hearing aid and using an assistive listening device at lectures, movies, and theater performances are helpful. Furthermore, recall from Chapter 4 (pages 143–144) that beginning at birth, our perception is *intermodal* (combines information from more than one sensory system). By attending to facial expressions, gestures, and lip movements, older adults can use vision to help interpret the spoken word. Finally, when family members and others speak in quiet environments, older people are far more likely to convey an image of alertness and competence than of reduced sensitivity to the surrounding world.

**Taste and Smell.** Walt's brother Dick was a heavy smoker. In his sixties, he poured salt and pepper over his food and asked for “extra hot” in Mexican and Indian restaurants.

Dick's reduced sensitivity to the four basic tastes—sweet, salty, sour, and bitter—is evident in more than half of adults after age 60 and up to 80 percent after age 80, largely due to a decline in number and distribution of taste buds on the tongue. Older adults also have greater difficulty recognizing familiar foods by taste alone (Correia et al., 2016; Methven et al., 2012). Cigarette smoking, dentures, medications, and environmental pollutants can affect taste perception. When taste is harder to detect, food is less enjoyable, increasing the likelihood of dietary deficiencies. Flavor additives can help make food more attractive.

Besides enhancing food enjoyment, smell has a self-protective function. An aging person who has difficulty detecting rancid food, gas fumes, or smoke may be in a life-threatening situation. A decrease in the number of smell receptors, along with loss of neurons in brain regions involved in processing odors, contributes to declines in odor sensitivity after age 60, with one-fourth of people over age 70 affected (Attems, Walker, & Jellinger, 2015; Correia et al., 2016). Researchers believe that odor perception not only wanes but becomes distorted, a change that may promote complaints that “food no longer smells and tastes right.” But older adults experiencing greater difficulty with verbal recall, including retrieval of odor labels, have greater difficulty with odor recognition tasks (Larsson, Öberg, & Bäckman, 2005). So cognitive changes may make the decline in odor perception appear greater than it actually is.

**Touch.** Object recognition through touch occurs many times each day, as adults identify common objects after manually exploring them—keys or credit card in a pocket, corkscrew at the back of a drawer—within 2 to 3 seconds. Touch discrimination is especially crucial for certain adults, such as the severely visually impaired reading Braille and people making fine judgments about texture—for example, in art and handicraft activities.

In later life, capacity to discriminate detailed surface properties and identify unfamiliar objects by touch declines. Waning of touch perception on the hands, especially the fingertips—believed to be due to loss of touch receptors in certain regions of the skin and slowing of blood circulation to the extremities—contributes (Stevens & Cruz, 1996). In addition, decrements in fluid abilities, especially spatial orientation, are influential (see page 526 in Chapter 15) (Kalisch et al., 2012). Fluid skills are strongly correlated with older adults' tactile performance.

Compared to their sighted counterparts, blind readers of Braille retain high touch sensitivity well into old age (Legge et al., 2008). Years of experience in picking up detailed tactile information seem to protect their tactile discrimination skills.

Although touch sensitivity typically diminishes in late adulthood, responsiveness to the emotionally pleasant quality of soft, gentle stroking is an exception: Older adults rate it as more pleasurable than younger people (Sehlstedt et al., 2016). Perhaps fewer touches from others in late life enhance enjoyment of sensitive touching when it happens.

## Cardiovascular and Respiratory Systems

Aging of the cardiovascular and respiratory systems proceeds gradually and usually unnoticed in early and middle adulthood. In late adulthood, changes become more apparent. In their sixties, Ruth and Walt noticed that they felt more physically stressed after running to catch a bus or to cross a street before the light changed.

As the years pass, the heart muscle becomes more rigid, and some of its cells die while others enlarge, leading the walls of the left ventricle (the largest heart chamber, from which blood is pumped to the body) to thicken. In addition, artery walls stiffen and accumulate some plaque (cholesterol and fats) due to normal aging (much more in those with atherosclerosis). Finally, the heart muscle becomes less responsive to signals from pacemaker cells within the heart, which initiate each contraction (Larsen, 2009).

As a combined result of these changes, the heart pumps with less force, maximum heart rate decreases, and blood flow throughout the circulatory system slows. This means that sufficient oxygen may not be delivered to body tissues during high physical activity. (Recall from Chapter 13 that a healthy heart supports typical levels of exertion well into old age.)

Changes in the respiratory system compound the effects of reduced oxygenation. Because lung tissue gradually loses its elasticity, vital capacity (amount of air that can be forced in and out of the lungs) is reduced by half between ages 25 and 80. As a result, the lungs fill and empty less efficiently, causing the blood

© JUICE IMAGES/ALAMY

These mountain hikers need frequent rests to catch their breath and regain their energy. With aging of the cardiovascular and respiratory systems, sufficient oxygen may not be delivered to body tissues during physical exertion.

to absorb less oxygen and give off less carbon dioxide. This explains why older people increase their breathing rate more and feel more out of breath while exercising.

Cardiovascular and respiratory deficiencies are more extreme in lifelong smokers and in people who have failed to reduce dietary fat or have had many years of exposure to environmental pollutants. As we have seen in previous chapters, exercise is a powerful means of slowing cardiovascular aging (Galetta et al., 2012). Exercise also facilitates respiratory functioning, as we will see later when we discuss health and fitness.

## Immune System

As the immune system ages, T cells, which attack antigens (foreign substances) directly, become less numerous and effective (see Chapter 13, page 443). In addition, the immune system is more likely to malfunction by turning against normal body tissues in an **autoimmune response**. A less competent immune system reduces the effectiveness of available vaccines and increases the risk of a variety of illnesses—in addition to infectious diseases (such as the flu), cardiovascular disease, certain forms of cancer, and various autoimmune disorders, such as rheumatoid arthritis and diabetes (Herndler-Brandstetter, 2014). But an age-related decline in immune functioning is not the cause of most late-life illnesses. It merely permits disease to progress, whereas a stronger immune reaction would stamp out the disease agent.

Although older adults vary greatly in immunity, most experience some loss, ranging from partial to profound (Ponnappan & Ponnappan, 2011). The strength of the aging person's immune system seems to be a sign of overall physical vigor. Certain immune indicators, such as high T cell activity, predict better physical functioning and survival over the next two years in very old people (Moro-García et al., 2012; Wikby et al., 1998).

Recall from Chapter 13 that stress hormones undermine immunity. With age, the autonomic nervous system releases higher levels of these into the bloodstream. As the immune response declines with age, stress-induced susceptibility to infection rises dramatically (Archer et al., 2011). A healthy diet and exercise help protect the immune response in old age, whereas obesity aggravates the age-related decline.

## Sleep

When Walt went to bed at night, he usually lay awake for a half-hour to an hour before falling asleep, remaining in a drowsy state longer than when he was younger. During the night, he spent less time in the deepest phase of NREM sleep (see Chapter 3, page 104) and awoke several times—again sometimes lying awake for a half-hour or more before drifting back to sleep.

Older adults require about as much total sleep as younger adults: around seven hours per night. Yet as people age, they have more difficulty falling asleep, staying asleep, and sleeping deeply. Insomnia affects about half of older adults. The timing of sleep tends to change as well, toward earlier bedtime and earlier morning waking (McCrae et al., 2015). Changes in brain structures controlling sleep and higher levels of stress hormones in the bloodstream, which have an alerting effect on the central nervous system, are believed to be responsible.

Until age 70 or 80, men experience more sleep disturbances than women, for several reasons. First, enlargement of the prostate gland, which occurs in almost all aging men, constricts the urethra (the tube draining the bladder) and leads to a need to urinate more often, including during the night. Second, men—especially those who are overweight and use alcohol heavily—are more prone to **sleep apnea**, a condition in which breathing ceases for 10 seconds or longer, resulting in many brief awakenings. An estimated 45 percent of older adults are affected (Okuro & Morimoto, 2014).

Poor sleep can feed on itself. Walt's nighttime wakefulness led to daytime fatigue and short naps, which made it harder to fall asleep the following evening. And because Walt expected to have trouble sleeping, he worried about it, which also interfered with sleep. Insomnia in older adults is of special concern because it increases the risk of falls and cognitive impairments (Crowley, 2011). Those who are poor sleepers more often report slower reaction times and attention and memory difficulties.

Fortunately, there are ways to foster restful sleep, such as establishing a consistent bedtime and waking time, exercising regularly, and using the bedroom only for sleep (not for eating, reading, or watching TV). Older adults receive more prescription sedatives for sleep complaints than do people under age 60. Used briefly, these drugs can help relieve temporary insomnia. But long-term medication can make matters worse by inducing drug dependence, daytime sleepiness, and rebound insomnia after the drug is discontinued (Wennberg et al., 2013). Finally, discomfort due to an enlarged prostate, including frequent urination at night, can be corrected with laser surgical procedures that relieve symptoms without complications (Zhang et al., 2012).

DAVID HUME KENNERLY/GETTY IMAGES

THE LIFE PICTURE COLLECTION/GETTY IMAGES

PHOTOSHOT/NEWSCOM

Aging brings changes in appearance, evident in these portraits of Jimmy Carter, former U.S. president, at ages 52, 63, and 91. The skin creases and sags, “age spots” increase, the nose and ears broaden, and hair on the head thins.

## Physical Appearance and Mobility

In earlier chapters, we saw that changes leading to an aged appearance are under way as early as the twenties and thirties. Because these occur gradually, older adults may not notice that they look older until the changes have become obvious. Each year during their summer travels, Walt and Ruth observed that Dick and Goldie’s skin appeared more wrinkled. Their hair turned from gray to white as all pigment was lost; their bodies grew rounder and their arms and legs thinner. When they returned home, Walt and Ruth were more aware that they themselves had aged.

Creasing and sagging of the skin, described in Chapter 15, extends into old age. In addition, oil glands that lubricate the skin become less active, leading to dryness and roughness. “Age spots” increase; in some individuals, the arms, backs of the hands, and face may be dotted with these pigmented marks. Blood vessels can be seen beneath the more transparent skin, which has largely lost its layer of fatty support (Robert, Labat-Robert, & Robert, 2009). This further limits ability to adapt to hot and cold temperatures.

The face is especially likely to show these effects, as it is frequently exposed to the sun, which accelerates aging. Other factors that contribute to facial wrinkling and age spots include long-term alcohol use, cigarette smoking, and psychological stress. Additional facial changes occur: The nose and ears broaden as new cells are deposited on the outer layer of the skeleton. And especially in older adults with a history of poor dental care, teeth may be yellowed, cracked, and chipped, and gums may have receded (Whitbourne, 2002). As hair follicles under the skin’s surface die, hair on the head thins in both sexes, and the scalp may be visible.

Body build changes as well. Height continues to decline, especially in women, as loss of bone mineral content leads to further collapse of the spinal column. Weight generally drops after age 60 because of additional loss of lean body mass (bone

density and muscle), which is heavier than the fat deposits accumulating on the torso.

Several factors affect mobility. The first is muscle strength, which generally declines at a faster rate in late adulthood than in middle age. On average, by 60 to 70 years of age, 10 to 20 percent of muscle power has been lost, a figure that climbs to 30 to 50 percent after age 70 to 80 (Reid & Fielding, 2012). Second, bone strength deteriorates because of reduced bone mass, and tiny cracks in response to stress weaken the bones further. Third, strength and flexibility of the joints and the ligaments and tendons (which connect muscle to bone) diminish. In her eighties, Ruth’s reduced ability to support her body, flex her limbs, and rotate her hips made walking at a steady, moderate pace, climbing stairs, and rising from a chair difficult.

In Chapter 13, we noted that endurance athletes who continue training throughout adulthood retain their muscular physiques and much of their strength into their sixties and seventies. These especially active people, like other aging individuals, lose fast-twitch muscle fibers. But they compensate by strengthening remaining slow-twitch fibers so they work more efficiently, yielding muscle function comparable to active people four decades younger (Sandri et al., 2014). Among nonathletes as well, a history of regular leisure time physical activity translates into greater mobility in late life (McGregor, Cameron-Smith, & Poppitt, 2014). At the same time, a carefully planned exercise program for older adults can enhance joint flexibility and range of movement.

## Adapting to Physical Changes of Late Adulthood

Great diversity exists in older adults’ adaptation to the physical changes of aging. People who are more anxious about growing older monitor their physical state more closely and are more concerned about their appearance (Montepare, 2006). Dick and

Goldie took advantage of an enormous industry designed to stave off outward signs of old age, including cosmetics, wigs, and plastic surgery, plus various “anti-aging” dietary supplements, herbal products, and hormonal medications offered by “longevity” clinics—none with any demonstrated benefits and some of them harmful (Olshansky, Hayflick, & Perls, 2004). In contrast, Ruth and Walt were relatively unconcerned about their thinning white hair and wrinkled skin. Their identities were less bound up with their appearance than with their ability to remain actively engaged in their surroundings.

Most older people sustain a favorable *subjective age*—say they feel younger than they look and than they actually are (Kleinspehn-Ammerlahn, Kotter-Grühn, & Smith, 2008; Westerhof, 2008). In several investigations, 75-year-olds reported feeling about 15 years younger! At follow-ups from a few years to two decades later, youthful self-evaluation predicted more favorable psychological well-being, better physical health and health behaviors, and slightly longer survival (Keyes & Westerhof, 2012; Westerhof et al., 2014).

Clearly, older adults vary in the aspects of physical aging that matter most to them. *Wanting* to be younger (as opposed to *feeling* younger) than one’s actual age is associated with less positive well-being (Keyes & Westerhof, 2012). Compared with Dick and Goldie, Ruth and Walt approached aging with a more positive outlook and greater peace of mind, resolving to intervene in those aspects of physical aging that could be changed and to accept those that could not.

Research shows that the most obvious outward signs of aging—graying hair, facial wrinkles, and baldness—bear no relationship to cognitive functioning or to longevity (Schnohr et al., 1998). In contrast, neurological, cardiovascular, respiratory, metabolic, immune-system, and skeletal and muscular health are strongly associated with cognitive performance and both quality and length of later life (Bergman, Blomberg, & Almkvist, 2007; Garcia-Pinillos et al., 2016; Herghelegiu & Prada, 2014; Qui, 2014). Furthermore, people can do more to prevent declines in the functioning of these internal body systems than they can do to prevent gray hair and baldness!

**Effective Coping Strategies.** Think back to our discussion of problem-centered and emotion-centered coping in Chapter 15. It applies here as well. As Walt and Ruth prevented and compensated for age-related changes through diet, exercise, environmental adjustments, and an active, stimulating lifestyle, they felt a sense of personal control over their fates. This prompted additional active coping and improved physical functioning.

Older people who report a high sense of personal control usually deal with physical changes through problem-centered coping strategies. One 75-year-old who lost sight in one eye consulted an occupational therapist for advice and, to compensate for reduced depth perception and visual field, trained himself to use more side-to-side head movements. In contrast, older adults who consider age-related declines inevitable and uncontrollable tend to be passive when faced with them, to report more physical and mental health difficulties, and to experience steeper late-life declines in health (Gerstorff et al., 2014; Lachman, Neupert, & Agrigoroaei, 2011; Ward, 2013).

Sense of control varies across cultures: U.S. individualistic values emphasize the power of one’s own actions and choices. Consequently, Americans score higher in personal control than adults in Asian nations and in Mexico (Angel, Angel, & Hill, 2009; Yamaguchi et al., 2005). Furthermore, we have seen that the United States is less generous than other industrialized nations in government-supported health care and social security benefits (see pages 64–65 in Chapter 2). In one study, sense of personal control was a stronger predictor of older adults’ health status in the United States than it was in England, where government policies do more to support good health throughout the lifespan (Clarke & Smith, 2011).

When physical disabilities become severe, sense of control has diminishing returns, no longer having as much impact on health status. Aging adults with substantial physical impairments cope more effectively when they acknowledge reduced control and accept the need for caregiver or equipment assistance (Clarke & Smith, 2011; Slagsvold & Sørensen, 2013). But doing so may be more difficult for many older Americans, who are accustomed to a “culture of personal control,” than for older people elsewhere in the world.

**Assistive Technology.** A rapidly expanding **assistive technology**, or array of devices that permit people with disabilities to improve their functioning, is available to help older people cope with physical declines. Computers and smart devices are the greatest sources of these innovative products (Czaja, 2016). Smartphones that respond to voice commands to make and answer calls help those with visual or motor difficulties. For older people who take multiple medications, a tiny computer chip called a “smart cap” can be placed on medicine bottles that beeps periodically as a reminder to take the drug and tracks how many and at what time pills have been taken. Smart watches and smart clothing can monitor diverse health indicators, improving prevention, early detection, and treatment. These devices can also recognize emergency situations, including falls, and summon help automatically. Robots are available that assist older adults with diverse tasks, such as retrieving objects, reading documents, and doing routine housework.

Architects have also designed homes that can adapt to changing physical needs—equipping them with movable walls that expand and contract, plumbing that enables a full bathroom to be added on the main floor, and “smart-home” technologies that promote safety and mobility, such as sensors in floors that activate room lights when an older person gets up at night, temperature sensors that detect whether the stove is left on, and alarm systems that detect falls. Another remarkable device is a bathroom scale that helps monitor health status. It sends a signal to a control box, which reads the person’s weight aloud. After comparing weight with previous readings, the box asks relevant questions—“Are you more tired than usual?” “Are you having trouble sleeping?”—that can be answered by pressing a “yes” or “no” button. The box also works with equipment that measures blood pressure, activity level, and other health indicators. Data collected are sent electronically to whomever the older adult gives access.

KEITH BUJAK

A robot hands medication to an adult with a physical disability, helping him sustain his independence and continue living in his own home.

Use of assistive devices slows physical declines and reduces the need for personal caregiving (Agree, 2014; Wilson et al., 2009). Do older people with disabilities regard some technologies as invasions of privacy? The majority weigh privacy concerns against potential benefits—saying, for example, “If this device would keep me independent longer, I wouldn’t mind” (Brown, Rowles, & McIlwain, 2016). Sustaining an effective *person–environment fit*, or match between older people’s current capabilities and the demands of their living environments, enhances psychological well-being (Lin & Wu, 2014).

At present, U.S. government-sponsored health-care coverage is largely limited to essential medical equipment; smart-home technologies are beyond the financial means of most older people. Sweden’s health-care system, in contrast, covers many assistive devices that promote function and safety, and its building code requires that new homes include a full bathroom on the main floor (Swedish Institute, 2016). In this way, Sweden strives to maximize person–environment fit for its older adults, helping them remain as independent as possible.

**Overcoming Stereotypes of Aging.** Negative stereotypes that view older adults as weak, boring, and debilitated and “deterioration as inevitable” are widespread in Western nations. Overcoming this pessimistic picture is vital for helping people adapt favorably to late-life physical changes. Many older adults report experiences of prejudice and discrimination (Perdue, 2016). These include being ignored, talked down to, or assumed to be unable to hear or understand, and exposure to disparaging jokes about older people.

Like gender stereotypes, aging stereotypes often operate automatically, without awareness; people “see” older adults in stereotypical ways, even when they appear otherwise (Kite et al., 2005). As older people encounter negative messages about aging, they experience *stereotype threat*, which results in diminished performance on tasks related to the stereotype (see page 320 in Chapter 9). In a growing number of studies, aging adults were

exposed to words associated with either negative aging stereotypes (“decrepit,” “confused”) or positive aging stereotypes (“sage,” “enlightened”). Those in negative-stereotype conditions displayed a more intense physiological response to stress, greater help-seeking and feelings of loneliness, and worse self-efficacy, physical performance, recall memory, and appraisals of their own health and memory capacity (Bouazzaoui et al., 2015; Coudin & Alexopoulos, 2010; Levy & Leifheit-Limson, 2009; Mazerolle et al., 2015). Stereotype threat triggers anxiety about one’s own abilities, depleting cognitive resources needed to perform well on tasks at hand.

The stressful, disorganizing impact of negative aging stereotypes can be long-lasting. In a longitudinal study lasting several decades, older people who endorsed many negative stereotypes displayed a 30 percent greater decline in memory performance than those who endorsed few stereotypes (Levy et al., 2012). The memory decrement was especially steep for individuals who viewed themselves as old—that is, for whom negative stereotypes were personally relevant.

Positive stereotypes, in contrast, reduce stress and foster physical and mental competence (Bolkan & Hooker, 2012). In another longitudinal investigation, people with positive self-perceptions of aging—who, for example, agreed with such statements as “As I get older, things are better than I thought they’d be”—lived, on average, 7½ years longer than those with negative self-perceptions. This survival advantage remained after gender, SES, loneliness, and physical health status were controlled (Levy et al., 2002). Adults with less education are especially susceptible to the detrimental effects of aging stereotypes, perhaps because they tend to accept those messages uncritically (Andreolletti & Lachman, 2004).

Older adults rarely appear in television programs, but when they do, they typically play minor roles and are portrayed as weak, unhealthy, or dependent. TV commercials aim to sell older people products and, therefore, usually depict them in stereotypically positive roles, most commonly as an “adventurous golden ager” (fun-loving, sociable, and active), “perfect grandparent” (family-oriented, kind, and generous), or “productive golden ager” (intelligent, capable, and successful) (Kotter-Grühn, 2015). Still, the products promoted in such ads are mostly medications and medical services and “anti-aging” cosmetics and treatments—images that reinforce negative views of older adults as preoccupied with physical declines and dissatisfied with their appearance.

In cultures where older adults are treated with deference and respect, aging can be a source of pride. In the native language of the Inuit people of Canada, the closest word to “elder” is *isumataq*, or “one who knows things”—a high status that begins when a couple becomes head of the extended family unit. When Inuit older adults were asked for their thoughts on aging well, they mentioned attitudes—a positive approach to life, interest in transmitting cultural knowledge to young people, and community involvement—nearly twice as often as physical health (Collings, 2001).

Japan honors its older citizens with an annual celebration, Respect for the Aged Day. Also, a ritual called *kanreki* recognizes

An older adult of the Inuit people of Canada lights a traditional oil lamp, a symbol of warmth and light in the arctic climate, as her granddaughter observes. Inuit culture confers high status on the aged, who serve as important sources of cultural knowledge for younger generations.

the older person's new freedoms and competencies and senior place in the family and society. Japanese extended families in the United States often plan the *kanreki* as a surprise sixtieth birthday party, incorporating elements of both the traditional ritual (such as dress) and the Western birthday (a special cake). A positive attitude toward aging prompts a welcoming approach to late adulthood, including some of its physical transitions.

Despite inevitable declines, physical aging can be viewed with either optimism or pessimism. As Walt commented, "You can think of your glass as half full or half empty." Cultural valuing of older adults greatly increases the likelihood that they will adopt the "half full" alternative.

## Ask yourself

**CONNECT** Review research on stereotype threat on page 320 in Chapter 9. How do stereotypes of aging similarly affect older adults' behavior?

**APPLY** "The best way to adjust to this is to learn to like it," thought 65-year-old Herman, inspecting his thinning hair in the mirror. "I remember reading that bald older men are viewed as leaders." What type of coping is Herman using, and why is it effective?

**REFLECT** While watching TV during the coming week, keep a log of portrayals of older adults in commercials. How many images were positive? How many negative? Compare your observations with research findings.

## Health, Fitness, and Disability

**17.5** Discuss health and fitness in late life, paying special attention to nutrition, exercise, and sexuality.

**17.6** Discuss physical disabilities associated with late adulthood.

**17.7** Discuss mental disabilities associated with late adulthood.

**17.8** Discuss health-care issues that affect older adults.

At Walt and Ruth's fiftieth wedding anniversary, 77-year-old Walt thanked a roomful of well-wishers for joining in the celebration. Then, with emotion, he announced, "I'm so grateful Ruth and I are still healthy enough to give to our family, friends, and community."

As Walt's remarks affirm, health is central to psychological well-being in late life. When researchers ask older adults about possible selves (see Chapter 16, page 544), number of hoped-for physical selves declines with age and number of feared physical selves increases. Nevertheless, because older people compare themselves to same-age peers, the majority rate their health favorably. And aging adults' self-rated health does not decline as much as would be expected on the basis of objective health assessments (French, Sargent-Cox, & Luszcz, 2012; U.S. Department of Health and Human Services, 2015d). As for protecting their health, older adults' sense of self-efficacy is as high as that of young adults and higher than that of middle-aged people (Frazier, 2002).

Self-efficacy and optimism about one's health promote continued health-enhancing behaviors and reduced incidence of chronic illness (Kubzansky & Boehm, 2016). Furthermore, disability need not inevitably lead to further disability and dependency. In longitudinal research, 10 to 50 percent of older adults with disabilities showed substantial improvement 2 to 6 years later (Johnston et al., 2004; Ostir et al., 1999).

SES continues to predict physical functioning. African-American and Hispanic older people (one-fifth of whom live in poverty) remain at greater risk for various health problems, including cardiovascular disease, diabetes, and certain cancers. Native-American aging adults are even worse off (Cubanski, Casillas, & Damico, 2015; Mehta, Sudharsanan, & Elo, 2014). The majority are poor, and chronic health conditions—including diabetes, kidney disease, liver disease, tuberculosis, and hearing and vision impairments—are so widespread that in the United States, the federal government grants Native Americans special health benefits. These begin as early as age 45, reflecting a much harder and shorter lifespan.

Unfortunately, low-SES and ethnic minority older adults are more likely than their higher-SES and white counterparts to delay or forgo medical treatment, particularly taking prescription medications and undergoing complex surgical procedures (Weech-Maldonado, Pradhan, & Powell, 2014). One reason is cost: On average, U.S. Medicare beneficiaries devote 18 percent of their income to out-of-pocket health-care expenses—a figure that escalates among those with the fewest resources

(Noel-Miller, 2015). Another reason is perceived discriminatory treatment by health-care providers, which undermines ethnic minority patients' trust (Guerrero, Mendes de Leon, & Evans, 2015). Furthermore, low-SES and minority older people often do not comply with doctors' directions because they feel less in control of their health and less optimistic that treatment will work. Their low self-efficacy further impairs their physical condition.

The sex differences noted in Chapter 15 extend into late adulthood: Men are more prone to fatal diseases, women to non-life-threatening disabling conditions—especially, mobility limitations due to osteoporosis and arthritis. By very old age (80 to 85 and beyond), women are more impaired than men because only the sturdiest men have survived (Deeg, 2016). In addition, with fewer physical limitations, older men are better able to remain independent and to engage in exercise, leisure and volunteer pursuits, and social activities, all of which promote better health.

Widespread health-related optimism among older people suggests that substantial inroads into preventing disability can be made even in the last few decades of life. Ideally, as life expectancy extends, we want the average period of diminished vigor before death—especially, the number of months or years of ill-health and suffering—to decrease. This public health goal is called the **compression of morbidity**. Several large-scale studies indicate that over the past several decades, compression of morbidity has occurred in industrialized nations (Fries, Bruce, & Chakravarty, 2011; Taylor & Lynch, 2011). Medical advances and improved socioeconomic conditions are largely responsible.

In addition, the impact of good health habits on postponement of disability is large. In one investigation, researchers followed a large sample of university alumni from their late sixties over the next two decades. In those who were low risk (no risk factors of smoking, obesity, or lack of exercise), disability was delayed by nearly 5 years compared with those who were moderate risk (had one of these risk factors). Compared to high-risk participants (with two or three risk factors), postponement of disability in the low-risk group exceeded 8 years (see Figure 17.3) (Chakravarty et al., 2012). Although good health habits lengthened life by about 3½ years, their impact on functional ability was greater.

Consequently, researchers believe that the most promising route to further compression of morbidity in developed countries is to reduce negative lifestyle factors. Progress in this respect, however, has been disappointing. Certain unhealthy conditions, such as a high-fat diet, overweight and obesity, and a sedentary lifestyle, have been increasing. Without modifying these factors, future gains in compression of morbidity will be hard to achieve. Rather, we may see a trend in the reverse direction: an *expansion of morbidity*, in which people live longer with debilitating illnesses because of improved medical treatments (Utz & Tabler,

**FIGURE 17.3** Development of disability in older adults with low, moderate, and high risk factors. More than 2,300 university alumni were followed from age 68 over the next two decades. The low-risk group had no risk factors (smoking, obesity, or lack of exercise). The moderate-risk group had one risk factor, and the high-risk group had two or three risk factors. Emergence of disability (at the 0.1 level) in the low-risk group was delayed by nearly 5 years compared to the moderate-risk group, and by more than 8 years compared to the high-risk group. Compression of morbidity occurred among the low-risk participants relative to their higher-risk counterparts, even though all participants were socioeconomically advantaged. (Adapted from E. F. Chakravarty et al., 2012, "Lifestyle Risk Factors Predict Disability and Death in Healthy Aging Adults," *American Journal of Medicine*, 125, p. 193. Copyright © 2012, Elsevier. Reprinted with permission from Elsevier, Inc.)

2016). As we look closely at health, fitness, and disability in late adulthood, we will add to our discussion of health promotion, taking up additional routes to this vital objective.

Comprehensive strategies are needed in the developing world, where 70 percent of older people will reside by 2025. In these nations, poverty is rampant, chronic diseases occur earlier, even routine health interventions are unavailable or too costly for many, and most public health programs do not focus on late adulthood (Rinaldo & Ferraro, 2012). As a result, disability rates among older adults are especially high, and as yet, no progress has been made in compression of morbidity.

## Nutrition and Exercise

The physical changes of late life lead to an increased need for certain nutrients—calcium and vitamin D to protect the bones; zinc and vitamins B<sub>6</sub>, C, and E to protect the immune system; and vitamins A, C, and E to protect against excess free radicals. Yet declines in physical activity, in the senses of taste and smell, and in ease of chewing (because of deteriorating teeth) can reduce the quantity and quality of food eaten. Furthermore, the aging digestive system has greater difficulty absorbing certain nutrients, such as protein, calcium, and vitamin D. And older adults who live alone may have problems shopping or cooking and may feel less like eating by themselves. Together, these physical and environmental conditions increase the risk of dietary deficiencies.

M.G. MOOI/HEMERA/GETTY IMAGES

A 70-year-old does abdominal exercises after going for a run. Previously sedentary older adults who engage in regular, moderate-to-vigorous exercise gain in muscle size and strength as well as executive function and memory.

Except for calcium and vitamin D, a daily vitamin–mineral supplement is recommended only for older adults suffering from malnutrition. Vitamin–mineral supplements do not reduce the incidence of cardiovascular disease or cancer (Neuhouser et al., 2009). Furthermore, supplemental nutrients and herbs identified as “cognitive enhancers”—including B and E vitamins, folic acid, and ginkgo biloba—do not improve cognitive functioning and neither prevent nor slow the progression of Alzheimer’s disease (DeKosky et al., 2008; McDaniel, Maier, & Einstein, 2002). Rather, a diet high in nutrients is most effective in fostering physical and cognitive health in late adulthood. And regularly eating fish high in omega-3 fatty acids (which aid cardiovascular health) offers some protection against mental disabilities (Cederholm, Salem, & Palmblad, 2013; Morris et al., 2016).

In addition to a healthy diet, exercise continues to be a powerful health intervention. Sedentary healthy older adults up to age 80 who begin endurance training (walking, cycling, aerobic dance) show gains in vital capacity that compare favorably with those of much younger individuals. And weight-bearing exercise begun in late adulthood—even as late as age 90—promotes muscle size and strength (deJong & Franklin, 2004; Pyka et al., 1994). This translates into improved walking speed, balance, posture, and ability to carry out everyday activities, such as opening a stubborn jar lid, carrying an armload of groceries, or lifting a 30-pound grandchild.

Exercise also increases blood circulation to the brain, which helps preserve brain structures and behavioral capacities. Brain scans show that physically fit older people experience less tissue loss—in both neurons and glial cells—in the cerebral cortex (Erickson et al., 2010; Miller et al., 2012). And compared with physically inactive age mates, previously sedentary older adults who initiated a program of regular, moderate to vigorous exercise displayed gains in size of diverse cortical areas, including the prefrontal cortex and hippocampus, with benefits for exec-

utive function and memory (Erickson, Leckie, & Weinstein, 2014). These findings offer clear biological evidence for the role of late-life physical activity in preserving central nervous system health.

Older people who come to value the intrinsic benefits of physical activity—feeling stronger, healthier, and more energetic—are likely to engage in it. Yet about 60 percent of U.S. 65- to 74-year-olds and 75 percent of those over age 75 do not exercise regularly (U.S. Department of Health and Human Services, 2015d). Often, those with chronic disease symptoms believe that exercise actually will do harm. In planning exercise programs for aging adults, it is important to instill a sense of control—by stressing the health-enhancing rewards of physical activity and by changing negative beliefs that interfere with sustained effort (Lachman, Neupert, & Agrigoroaei, 2011). Active older people can serve as positive role models and sources of encouragement for others.

## Sexuality

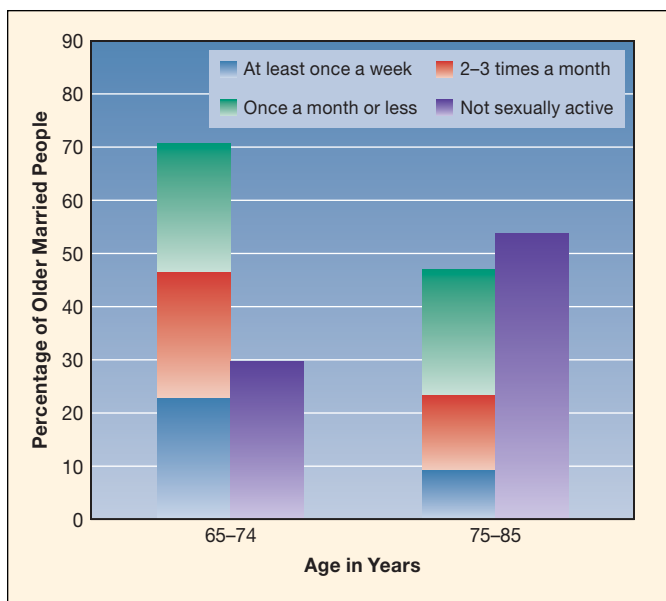

When Walt turned 60, he asked his 90-year-old Uncle Louie at what age sexual desire and activity cease. Walt’s question stemmed from a widely held myth that sex drive disappears in late adulthood. Louie corrected this impression. “My sexual interest has never gone away,” he explained to Walt. “I can’t do it as often, and it’s a quieter experience than it was in my youth. But Rachella and I have led a happy intimate life, and it’s still that way.”

As in other surveys of large, nationally representative samples of U.S. older people, the National Social Life, Health, and Aging Project revealed an age-related decline in frequency of sexual activity—especially among women, who are less likely

JONATHAN KIRN/GETTY IMAGES

Most married older adults report continued, regular sexual enjoyment. In addition to intercourse, feeling sensual, enjoying close companionship, and being loved and wanted are all part of sexuality at the most advanced ages.

**FIGURE 17.4** Age-related changes in sexual activity among U.S. married older adults. In the National Social Life, Health, and Aging Project, which included 1,500 married U.S. older people, most reported engaging in sexual activity at least two to three times per month. Sexual activity declined with age. Still, nearly half of 75- to 85-year-olds were sexually active. (Based on Karraker & DeLamater, 2013.)

than men to be in a marital or other intimate relationship. At the same time, the majority of respondents attributed at least some importance to sex, and those who had been sexually active in the previous year mostly rated sex as “very” or “extremely” important. Consistent with these attitudes, most married older adults reported continued, regular sexual enjoyment. Nearly half of the oldest survey participants, age 75 to 85, were sexually active, with more than 20 percent indicating that they engaged in some type of sexual activity (usually intercourse) at least two to three times per month (see Figure 17.4) (Karraker & DeLamater, 2013). Note that these trends are probably influenced by cohort effects: A new generation of older people, accustomed to viewing sexuality positively, will probably be more sexually active.

The same generalizations we discussed for midlife apply to late life: Good sex in the past predicts good sex in the future, and continued sexual activity is linked to relationship satisfaction. Furthermore, using intercourse as the only measure of sexual activity promotes a narrow view of pleasurable sex. Even at the most advanced ages, there is more to sexuality than the sex act itself—feeling sensual, enjoying close companionship, and being loved and wanted. Both older men and older women report that the male partner is usually the one who ceases to interact sexually (DeLamater, 2012; Karraker & DeLamater, 2013). In a culture that emphasizes an erection as necessary for being sexual, a man may withdraw from all erotic activity when he finds that erections are harder to achieve and more time must elapse between them.

Disabilities that disrupt blood flow to the penis—most often, disorders of the autonomic nervous system, cardiovascular disease, and diabetes—are largely responsible for dampening

sexuality in older men. But as noted in Chapter 15, availability of drug treatments, such as Viagra, has increased men’s willingness to discuss erectile dysfunction with their doctors. Cigarette smoking, excessive alcohol intake, mental health problems such as persistent anxiety and depression, and a variety of prescription medications also lead to diminished sexual performance. Among women, poor physical and mental health and absence of a partner are major factors that reduce sexual activity (DeLamater, 2012; DeLamater & Koepsel, 2014). Because the sex ratio increasingly favors females, aging heterosexual women have fewer and fewer opportunities for sexual encounters. Older adults who lack partners for an extended time tend to drift into a state of sexual disinterest.

The little evidence available on lesbian and gay older adults resembles findings on heterosexual individuals: Those who are married or in a committed relationship are more sexually active. And as sexual minority couples grow old, their focus shifts from sexual acts that lead to climax to those that convey deep affection, such as kissing, embracing, caressing, and sleeping together (Slevin & Mowery, 2012).

In Western industrialized nations, sexual expression in old age frequently meets with disapproval. Educational programs that inform older people about typical age-related changes in sexual functioning and that promote a view of sex as extending throughout adulthood are vital for encouraging positive sexual attitudes. In nursing homes, education for caregivers can help ensure residents’ rights to privacy and other living conditions that permit sexual activity (DeLamater & Koepsel, 2014). A special need exists to increase staff acceptance of sexual contact between lesbian and gay couples.

## Physical Disabilities

Compare the death rates shown in Figure 17.5 with those in Figure 15.3 on page 516. You will see that illness and disability

**FIGURE 17.5** Leading causes of death among people age 65 and older in the United States. In late adulthood, heart disease and cancer are leading causes of death. Stroke, chronic respiratory diseases, and Alzheimer’s disease also claim the lives of many older adults. Women exceed men in deaths due to stroke and Alzheimer’s disease. (Based on Heron, 2015.)

climb as the end of the lifespan approaches. Heart disease and cancer remain the leading causes of death, increasing dramatically from mid- to late life. As before, death rates from heart disease and cancer are higher for men than for women (Heron, 2015).

Respiratory diseases, which rise sharply with age, are the third most common cause of death among older adults. Among such diseases is *emphysema*, caused by extreme loss of elasticity in lung tissue, which results in serious breathing difficulty. Although a few cases of emphysema are inherited, most result from long-term cigarette smoking. *Stroke* and *Alzheimer's disease* follow; both are unique in being more prevalent among women, largely because women live longer. Stroke occurs when a blood clot blocks a blood vessel or a blood vessel hemorrhages in the brain, causing damage to brain tissue. It is a major cause of late-life disability and, after age 75, death. Alzheimer's disease, the leading cause of dementia, also rises sharply with age; we will consider it in-depth shortly.

Other diseases are less frequent killers, but they limit older adults' ability to live fully and independently. We have already noted the increase after age 65 in macular degeneration, which severely impairs vision and leads to blindness (see page 575). Osteoporosis, discussed in Chapter 15, continues to rise in late adulthood; recall that it affects the majority of men and women after age 70. Yet another bone disorder—*arthritis*—adds to the physical limitations of many older people. And *type 2 diabetes* and *unintentional injuries* also multiply in late adulthood. In the following sections, we take up these last three conditions.

Finally, an important point must be kept in mind as we discuss physical and mental disabilities of late adulthood: That these conditions are strongly *related to age* does not mean that they are *entirely caused by aging*. To clarify this distinction, experts distinguish between **primary aging** (another term for *biological aging*), or genetically influenced declines that affect all members of our species and take place even in the context of overall good health, and **secondary aging**, declines due to hereditary defects and negative environmental influences, such as poor diet, lack of exercise, disease, substance abuse, environmental pollution, and psychological stress.

Throughout this book, we have seen that it is difficult to distinguish primary from secondary aging. Undoubtedly you have, at one time or another, encountered *frail older adults*—people with extreme infirmity who display wasted muscle mass and strength, weight loss, severe mobility problems, and perhaps cognitive impairment. **Frailty** involves weakened functioning of diverse organs and body systems, yielding symptoms that profoundly interfere with everyday competence—unintentional weight loss, self-reported exhaustion, muscle weakness, slow walking speed, and low physical activity. Frailty leaves older people highly vulnerable in the face of infection, extremely hot or cold weather, or injury (Moorehouse & Mallery, 2016). Although primary aging contributes to frailty, researchers agree that secondary aging plays a larger role, through genetic disorders, unhealthy lifestyle (including obesity and sedentary behavior), and chronic disease (Fried et al., 2009; Song et al.,

© SEAN SPRAGUE/ALAMY

The frail older adult on the left has limited mobility that interferes with her everyday competence. Although biological aging contributes to frailty, secondary aging plays a larger role.

2015). The serious conditions we are about to discuss are major sources of frailty in late adulthood.

**Arthritis.** Beginning in her late fifties, Ruth felt a slight morning stiffness in her neck, back, hips, and knees. In her sixties, she developed bony lumps on the end joints of her fingers. As the years passed, she experienced joint pain, swelling, and some loss of flexibility—changes that affected her ability to move quickly and easily.

Arthritis, a condition of inflamed, painful, stiff, and sometimes swollen joints and muscles, becomes more common in late adulthood. It occurs in several forms. Ruth has **osteoarthritis**, the most common type, which involves deteriorating cartilage on the ends of bones of frequently used joints. Otherwise known as “wear-and-tear arthritis” or “degenerative joint disease,” it is one of the few age-related disabilities in which years of use make a difference. Although a genetic proneness exists, the disease usually does not appear until the forties or fifties. In frequently used joints, cartilage on the ends of the bones, which reduces friction during movement, gradually deteriorates. Or obesity places abnormal pressure on the joints and damages cartilage. Almost all older adults show some osteoarthritis on X-rays, although wide individual differences in severity exist (Baker & Mingo, 2016). It is the most common cause of mobility problems and of surgical hip and knee replacements in older adults.

Unlike osteoarthritis, which is limited to certain joints, **rheumatoid arthritis** involves the whole body. An autoimmune response leads to inflammation of connective tissue, particularly the membranes that line the joints, resulting in overall aching, inflammation, and stiffness. Tissue in the cartilage tends to grow, damaging surrounding ligaments, muscles, and bones. The result is deformed joints and often serious loss of mobility. Sometimes other organs, such as the heart and lungs, are affected (Goronzy, Shao, & Weyand, 2010). Worldwide, about ½ to 1 percent of older adults have rheumatoid arthritis.

Overall, 45 percent of U.S. men over age 65 have been diagnosed with arthritis, about 20 percent of whom experience disability due to the disease. Among women age 65 and older, the disease incidence is higher, at 55 percent, and so is the rate of disability among diagnosed individuals, at 25 percent (Hootman et al., 2016). Although rheumatoid arthritis can strike at any age, it increases after age 60. Twin studies support a strong hereditary contribution. Presence of certain genes heightens disease risk, possibly by triggering a late-life defect in the immune system (Frisell, Saevarsdottir, & Askling, 2016; Yarwood et al., 2015). However, identical twins differ widely in disease severity, indicating that environment makes a difference. So far, cigarette smoking is the only confirmed lifestyle influence, greatly increasing risk in people without a family history of the disease (Di Giuseppe et al., 2014). Early treatment with powerful anti-inflammatory medications helps slow progression of rheumatoid arthritis.

Managing arthritis requires a balance of rest when the disease flares, pain relief, and physical activity. Regular aerobic exercise and strength training lessen pain and improve physical functioning (Semanik, Chang, & Dunlop, 2012). In obese people, weight loss is essential. Although osteoarthritis responds to these interventions more easily than rheumatoid arthritis, the course of each varies greatly. With proper analgesic medication, joint protection, lifestyle changes, and surgery to replace badly damaged hip or knee joints, many people with either form of the illness lead long, productive lives.

**Diabetes.** After a meal, the body breaks down the food, releasing glucose (the primary energy source for cell activity) into the bloodstream. Insulin, produced by the pancreas, keeps the blood concentration of glucose within set limits by stimulating muscle and fat cells to absorb it. When this balance system fails, either because not enough insulin is produced or because body cells become insensitive to it, *type 2 diabetes* (otherwise known as *diabetes mellitus*) results. Over time, abnormally high blood glucose damages the blood vessels, increasing the risk of heart attack, stroke, circulatory problems in the legs (which impair balance and gait), and injury to the eyes, kidneys, and nerves.

Impaired glucose tolerance also accelerates degeneration of neurons and synapses (Petrofsky, Berk, & Al-Nakhli, 2012). In several longitudinal studies, diabetes was associated with more rapid cognitive declines in older people and an elevated risk of dementia, especially Alzheimer's disease—an association we will soon revisit when we take up Alzheimer's (Baglietto-Vargas et al., 2016; Cheng et al., 2012). Cognitive deficits may even be under way in the prediabetic state, prior to a diabetic diagnosis.

From middle to late adulthood, the incidence of type 2 diabetes nearly doubles; it affects one-fourth of Americans age 65 and older (Centers for Disease Control and Prevention, 2014c). Diabetes runs in families, suggesting that heredity is involved. But inactivity and abdominal fat deposits greatly increase the risk. Higher rates of type 2 diabetes are found among African-American, Mexican-American, and Native-American aging adults for both genetic and environmental reasons, including

high-fat diets and obesity associated with poverty. More than one-third have the disease.

Treating type 2 diabetes requires lifestyle changes, including a carefully controlled diet and regular exercise, which promote weight loss and glucose reabsorption. In many people with recent disease onset (less than one year), sustaining these behaviors partially or completely reverses the course of the illness (Ades, 2015).

**Unintentional Injuries.** At age 65 and older, the death rate from unintentional injuries is at an all-time high—more than twice as great as in adolescence and early adulthood. Motor vehicle collisions and falls are largely responsible.

**Motor Vehicle Accidents.** Motor vehicle collisions account for just 15 percent of U.S. injury mortality in late life, compared with 50 percent in middle adulthood. But a look at individual drivers tells a different story. Older adults have higher rates of traffic violations, accidents, and fatalities per mile driven than any other age group, with the exception of drivers under age 25. The high rate of injury persists, even though many older people, especially women, limit their driving after noticing that their ability to drive safely is slipping (Heron, 2015). Deaths due to injuries—motor vehicle and otherwise—continue to be much higher for men than for women.

Recall that visual declines led Walt to have difficulty seeing the dashboard and identifying pedestrians at night. The greater older adults' visual processing difficulties, the higher their rate of moving violations and crashes (Friedman et al., 2013). Compared with young drivers, older people are less likely to drive quickly and recklessly but more likely to fail to heed signs, yield the right of way, and turn appropriately. They often try to compensate for their difficulties by being more cautious. Slowed reaction time and indecisiveness pose hazards, too. In Chapter 15, we noted that executive function declines with age: Tasks requiring spatial working memory, inhibition of irrelevant

Visual processing difficulties, slowed reaction time, and declines in executive function contribute to high rates of traffic violations, accidents, and fatalities per mile driven in late adulthood. Still, aging adults usually try to drive as long as possible.

information and impulses, and flexible shifting of attention between activities become increasingly challenging (see page 528). Because these skills are essential for safe driving, aging adults are at high risk for collisions at busy intersections and in other complex traffic situations.

Nevertheless, older people usually try to drive as long as possible. Giving up driving results in loss of personal control over daily life and decline in productive roles, such as paid work and volunteering (Curl et al., 2014). Specially trained driver rehabilitation consultants—affiliated with hospitals, drivers licensing agencies, or U.S. Area Agencies on Aging (see page 65 in Chapter 2)—can help assess older adults' capacity to continue driving, provide driver retraining, or counsel them to retire from driving and use other transportation options.

Aging adults also make up nearly 20 percent of all U.S. pedestrian deaths (Centers for Disease Control and Prevention, 2016f). Confusing intersections, especially signals that do not allow older people enough time to cross the street, are often involved.

**Falls.** One day, Ruth fell down the basement steps and lay there with a broken ankle until Walt arrived home an hour later. Ruth's tumble represents the leading type of accident in late life. About one-third of adults over age 65 and half of those over age 80 have experienced a fall within the past year (Centers for Disease Control and Prevention, 2016c). Declines in vision, hearing, mobility, muscle strength, and cognitive functioning; depressed mood; use of medications that affect mental processing; and development of certain chronic illnesses, such as arthritis—all of which make it harder to avoid hazards and keep one's balance—increase the risk of falling (Rubenstein, Stevens, & Scott, 2008). The more of these factors that are present, the greater the risk of falling.

Because of weakened bones and difficulty breaking a fall, serious injury results about 20 percent of the time. The most common is hip fracture. It increases fifteenfold from age 65 to 85 and frequently leads to reduced mobility, increased weakness, and serious health complications. One in five older hip fracture patients dies within a year of the injury (Centers for Disease Control and Prevention, 2015f). Of those who survive, half never regain the ability to walk without assistance.

Falling can also impair health indirectly, by promoting fear of falling. Nearly half of older adults who have fallen admit that they purposefully avoid activities because they are afraid of falling again. In this way, a fall can limit mobility and social contact, undermining both physical and psychological well-being (Painter et al., 2012). Although an active lifestyle may expose older people to more situations that can cause a fall, the health benefits of activity far outweigh the risk of serious injury due to falling.

**Preventing Unintentional Injuries.** Many steps can be taken to reduce unintentional injury in late adulthood. Designing motor vehicles and street signs to accommodate older adults' visual needs is a goal for the future. Meanwhile, training that enhances visual and cognitive skills essential for safe driving and that helps older adults avoid high-risk situations (such as busy intersections and rush hour) can save lives.

Similarly, efforts to prevent falls must address risks within the person and the environment—through corrective eyewear, strength and balance training, and improved safety in homes and communities. Consult the National Resource Center for Safe Aging, [www.safeaging.org](http://www.safeaging.org), for a wealth of information on safety in late adulthood.

## Mental Disabilities

Normal age-related cell death in the brain, described earlier, does not lead to loss of ability to engage in everyday activities. But when cell death and structural and chemical abnormalities are profound, serious deterioration of mental and motor functions occurs.

**Dementia** refers to a set of disorders occurring almost entirely in old age in which many aspects of thought and behavior are so impaired that everyday activities are disrupted. Dementia strikes 13 percent of adults over age 65. Approximately 2 to 3 percent of people age 65 to 69 are affected; the rate doubles every 5 to 6 years until it reaches about 22 percent among those age 85 to 89 and over half after age 90—trends that apply to the United States and other Western nations (Prince et al., 2013). Beyond age 80, a larger proportion of women than men have dementia, perhaps reflecting the biological sturdiness of the oldest men. Although dementia rates are similar across most ethnic groups, older African Americans have about twice the incidence, and Hispanics about one and one-half times the incidence, as whites (Alzheimer's Association, 2016a). Associated risk factors, not race, are responsible, as we will see shortly.

About a dozen types of dementia have been identified. Some are reversible with proper treatment, but most are irreversible and incurable. A few forms, such as Parkinson's disease,<sup>1</sup> involve deterioration in subcortical brain regions (primitive structures below the cortex) that often extends to the cerebral cortex and, in many instances, results in brain abnormalities resembling Alzheimer's disease. Research suggests that Parkinson's and Alzheimer's are related (Goedert, 2015). But in the majority of dementia cases, subcortical brain regions are intact, and progressive damage occurs only to the cerebral cortex. The two most common forms of *cortical dementia* are Alzheimer's disease and vascular dementia.

**Alzheimer's Disease.** When Ruth took 79-year-old Ida to the ballet, an occasion the two sisters eagerly anticipated each year, she noticed a change in Ida's behavior. Ida, who had forgotten the engagement, reacted angrily when Ruth arrived unannounced at her door. Driving to the theater, which was in a familiar part of town, Ida got lost—all the while insisting that she knew the way perfectly. As the lights dimmed and the music began, Ida talked loudly and dug noisily in her purse.

<sup>1</sup>In Parkinson's disease, neurons in the part of the brain that controls muscle movements deteriorate. Symptoms include tremors, shuffling gait, loss of facial expression, rigidity of limbs, difficulty maintaining balance, and stooped posture. Over time, the disease often results in dementia.

“Shhhhhh,” responded a dozen voices from surrounding seats.

“It’s just the music!” Ida snapped at full volume. “You can talk all you want until the dancing starts.” Ruth was astonished and embarrassed at the behavior of her once socially sensitive sister.

Six months later, Ida was diagnosed with **Alzheimer’s disease**, the most common form of dementia, in which structural and chemical brain deterioration is associated with gradual loss of many aspects of thought and behavior. Alzheimer’s accounts for an estimated 70 percent of all dementia cases. Approximately 11 percent of Americans over age 65—about 5.2 million people—have the disorder. Of those over age 85, about one-third are affected. In 2030, when all baby boomers will have reached late adulthood, the number of Americans with Alzheimer’s is expected to rise to 7.7 million—an increase of more than 50 percent. About 5 to 15 percent of all deaths among older adults involve Alzheimer’s, making it a significant cause of late-life mortality (Alzheimer’s Association, 2016a).

**Symptoms and Course of the Disease.** The earliest symptoms are often progressively worsening memory problems—forgetting names, dates, appointments, familiar routes of travel, or the need to turn off the kitchen stove. At first, recent memory is most impaired (Bilgel et al., 2014). But as serious disorientation sets in, recall of distant events and such basic facts as time, date, and place evaporates. Faulty judgment puts the person in danger. For example, Ida insisted on driving after she was no longer competent to do so. Personality changes occur—loss of spontaneity and sparkle, anxiety in response to uncertainties created by mental problems, aggressive outbursts, reduced initiative, and social withdrawal. Depression often appears in the early phase of Alzheimer’s and other forms of dementia and seems to be part of the disease process (Serra et al., 2010). However, depression may worsen as the older adult reacts to disturbing mental changes.

As the disease progresses, skilled and purposeful movements disintegrate. When Ruth took Ida into her home, she had to help her dress, bathe, eat, brush her teeth, and (eventually) walk and use the bathroom. Ida’s sleep was disrupted by delusions and imaginary fears. She often awoke in the night and banged on the wall, insisting that it was dinnertime, or cried out that someone was choking her. Over time, Ida lost the ability to comprehend and produce speech. And when her brain ceased to process information, she could no longer recognize objects and familiar people. In the final months, Ida became increasingly immobile, vulnerable to infections, lapsed into a coma, and died.

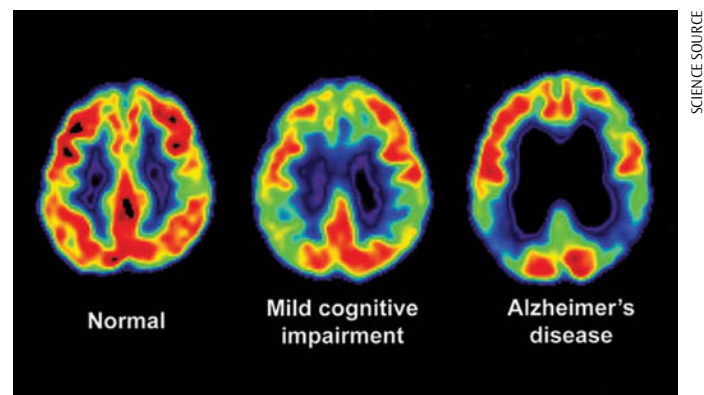

The course of Alzheimer’s varies greatly, from a year to as long as 20 years, with those diagnosed in their sixties and early seventies typically surviving longer than those diagnosed at later ages (Brodaty, Seeher, & Gibson, 2012). The average life expectancy for a 70-year-old man with the disease is about 4½ years, for a 70-year-old woman about 8 years.

**Brain Deterioration.** A diagnosis of Alzheimer’s disease is made through exclusion, after ruling out other causes of

dementia by a physical examination and psychological testing—an approach that is more than 90 percent accurate. To confirm Alzheimer’s, doctors inspect the brain after death for a set of abnormalities that either cause or result from the disease (Hyman et al., 2012). In about 90 percent of cases, however, MRI and PET images of brain volume and activity predict whether individuals will receive an after-death confirmation of Alzheimer’s (Vitali et al., 2008). Assessments of the chemical makeup of the blood or cerebrospinal fluid are also strongly predictive (Mattsson et al., 2015; Olsson et al., 2016). These procedures offer hope of very early diagnosis, opening the door to more successful interventions.

Two major structural changes in the cerebral cortex, especially in memory and reasoning areas, are associated with Alzheimer’s. Inside neurons, **neurofibrillary tangles** appear—bundles of twisted threads that are the product of collapsed neural structures and that contain abnormal forms of a protein called tau. Outside neurons, **amyloid plaques**, dense deposits of a deteriorated protein called *amyloid*, surrounded by clumps of dead neurons and glial cells, develop. Although some neurofibrillary tangles and amyloid plaques are present in the brains of normal middle-aged and older people and increase with age, they are far more abundant in Alzheimer’s victims. A major thrust of current research is understanding exactly how abnormal amyloid and tau damage neurons, so treatments can be developed to slow or block these processes.

Researchers once thought that amyloid plaques contributed to the neuronal damage of Alzheimer’s. But recent findings suggest that they reflect the brain’s effort to get harmful amyloid away from neurons. Instead, a major culprit seems to be abnormal breakdown of amyloid remaining *within* neurons (National Institute on Aging, 2016). In both Alzheimer’s disease and Parkinson’s disease, disruptions occur in a key neuronal process responsible for chopping up and disposing of abnormal proteins (Sagare et al., 2013). These damaged proteins (including amyloid) build to toxic levels. Abnormal amyloid causes the

These PET images contrast a normal brain (left) with those showing structural and chemical deterioration. With widespread synaptic damage and neuronal death, overall brain volume decreases and the ventricles expand. Mild cognitive impairment (center) commonly precedes a more dramatic decline in brain volume (right), which is highly predictive of an after-death confirmation of Alzheimer’s disease.

An image of tissue in the Alzheimer's brain reveals amyloid plaques between neurons, and dead and dying neurons containing neurofibrillary tangles. Compare these cell changes with healthy brain cells.

generation of signals within neurons and their transfer across synapses to malfunction (Kopeikina et al., 2011). Eventually, damaged amyloid induces heightened, abnormal electrical activity throughout the brain, contributing to broad neural network malfunctioning.

Abnormal tau in neurofibrillary tangles adds to neuronal breakdown. Tangles disrupt the transport of nutrients and signals from the neuron to its connective fibers, thereby joining with amyloid to block synaptic communication. Furthermore, abnormal tau triggers disintegration of nearby normal tau (de Calignon et al., 2012; Liu et al., 2012). Gradually, tau pathology moves across synapses, spreading from neuron to neuron and, over time, from one brain region to the next—thereby amplifying damage.

As synapses deteriorate, levels of neurotransmitters decline, neurons die in massive numbers, and brain volume shrinks. Destruction of neurons that release the neurotransmitter acetylcholine, involved in transporting messages between distant brain regions, further disrupts neuronal networks. A drop in serotonin, a neurotransmitter that regulates arousal and mood, may contribute to sleep disturbances, aggressive outbursts, and depression (Rothman & Mattson, 2012). These problems may intensify cognitive and motor symptoms.

**Risk Factors.** Alzheimer's disease comes in two types: *familial*, which runs in families, and *sporadic*, which has no obvious family history. Familial Alzheimer's, responsible for 1 percent or fewer cases, generally has an early onset—between ages 30 and 60—and progresses more rapidly than the later-appearing sporadic type, which typically appears after age 65. Researchers have identified genes on chromosomes 1, 14, and 21, involved in generation of harmful amyloid, that are related to familial Alzheimer's. In each case, the abnormal gene is dominant; if it is present in only one of the pair of genes inherited from parents, the person will develop early-onset Alzheimer's (National Institute on Aging, 2016). Recall that chromosome 21

is involved in Down syndrome. Individuals with this chromosomal disorder who live past age 40 almost always have the brain abnormalities and symptoms of Alzheimer's.

Heredity plays a different role in sporadic Alzheimer's, through somatic mutation. About half of people with this form of the disease have an abnormal gene on chromosome 19, which results in excess levels of APOE  $\epsilon$ 4, a blood protein that carries cholesterol throughout the body. Researchers believe that a high blood concentration of APOE  $\epsilon$ 4 affects the expression of a gene involved in regulating insulin. Deficient insulin and resulting glucose buildup in the bloodstream (conditions that, when extreme, lead to diabetes) are linked to brain damage, especially in areas regulating memory, and to high buildup of harmful amyloid in brain tissue (Liu et al., 2013; National Institute on Aging, 2016). In line with these findings, individuals with diabetes have a greatly increased risk of developing Alzheimer's.

At present, the abnormal APOE  $\epsilon$ 4 gene is the most widely known risk factor for sporadic Alzheimer's: Those who inherit one APOE  $\epsilon$ 4 allele have a threefold greater risk; those who inherit two alleles have an eight- to twelvefold greater risk (Loy et al., 2014). But genetic testing has revealed many other genes that seem to make an equal or greater contribution. For example, in older adults with Alzheimer's, genes involved in clearing abnormal proteins from neurons often are altered, enabling excessive amyloid and tau buildup. And some genes impair nutrient and signal transfer from neurons to connective fibers, without affecting amyloid (National Institute on Aging, 2016).

Nevertheless, many sporadic Alzheimer's victims show no known genetic marker, and some individuals with the APOE  $\epsilon$ 4 gene do not develop the disease. Evidence is increasing for the role of a variety of largely modifiable risk factors, including excess dietary fat, physical inactivity, overweight and obesity, smoking, chronic depression, cardiovascular disease, stroke, and (as just noted) diabetes (Baumgart et al., 2015; Institute of Medicine, 2015). Moderate to severe head injuries, possibly by accelerating deterioration of amyloid and tau, also increase Alzheimer's risk, especially among people with the APOE  $\epsilon$ 4 gene (Mckee & Daneshvar, 2015). Although a single injury is sufficient for long-term, debilitating consequences, individuals subjected to repeated instances, such as boxers, football players, and combat veterans, are especially likely to be affected.

Still, some older adults with an abundance of amyloid plaques in their brains never develop Alzheimer's. The disease is believed to result from different combinations of genetic and environmental factors, each leading to a somewhat different course of the disease. The high incidence of Alzheimer's and other forms of dementia among African Americans illustrates the complexity of potential causes.

Compared with African Americans, Yoruba village dwellers of Nigeria show a much lower Alzheimer's incidence and a much weaker association between the APOE  $\epsilon$ 4 gene and the disease (Hendrie et al., 2014). Some investigators speculate that intermarriage with European Americans heightened genetic risk among African Americans and that environmental factors translated that risk into reality. Whereas the Yoruba of Nigeria eat a

low-fat diet, the African-American diet is high in fat. Eating fatty foods may increase the chances that the APOE  $\epsilon$ 4 gene will lead to Alzheimer's. And even for Yoruba and African Americans without the APOE  $\epsilon$ 4, a high-fat diet is risky (Hall et al., 2006). The more fat consumed and the higher the blood level of “bad” cholesterol (low-density lipoproteins), the greater the incidence of Alzheimer's.

New findings indicate that a substantial number of sporadic Alzheimer's cases are due to epigenetic processes, in which environmental influences modify gene expression (see page 70 in Chapter 2). In one study, researchers examined over 700 donated brains of older adults who had died. In many brains with Alzheimer's abnormalities, elevated methylation levels, which reduce or silence a gene's impact, were linked to genetic markers of the disease and predicted extent of amyloid plaque buildup (De Jager et al., 2014). The next step is to identify factors that trigger gene methylation associated with the disease.

**Protective Factors.** Researchers are testing both drug and nondrug approaches to preventing or slowing the progress of Alzheimer's. Among promising drug therapies are compounds that interfere with amyloid and tau breakdown and that suppress brain inflammation resulting from these toxic proteins, which worsens neuronal damage (Bachstetter, Watterson, & Van Eldik, 2014; Lou et al., 2014). Insulin therapy, delivered via a nasal spray to the brain, helps regulate neuronal use of glucose (Ribarič, 2016). Research indicates that it has memory benefits and slows cognitive decline, at least in the short term, among older adults with *mild cognitive impairment*—diminished mental abilities that are noticeable to the affected person, friends, and family members but that do not affect capacity to carry out everyday activities, which commonly precede Alzheimer's.

A “Mediterranean diet” emphasizing fish, unsaturated fat (olive oil), vegetables, and moderate consumption of red wine is linked to a 30 to 50 percent reduced incidence of Alzheimer's disease, to slower disease progression in diagnosed individuals, and also to a reduction in vascular dementia (which we will turn to next) (Lourida et al., 2013; Morris et al., 2015). These foods contain antioxidants and other substances that help promote the health of the cardiovascular and central nervous systems.

Education and an active lifestyle are beneficial as well. The rate of Alzheimer's is reduced by more than half in older adults with higher education, though this protective effect is not as great for those with the APOE  $\epsilon$ 4 gene (Beydoun et al., 2014). Some researchers speculate that complex cognitive activities of better-educated people lead to reorganization of brain areas devoted to cognitive processes and to richer synaptic connections, which act as a **cognitive reserve**, giving the aging brain greater tolerance for injury before it crosses the threshold into mental disability. In support of this view, compared to their less-educated counterparts, the highly educated display a faster rate of decline following an Alzheimer's or other dementia diagnosis, suggesting that they show symptoms only after very advanced brain deterioration (Karbach & Küper, 2016). Late-life cognitively stimulating social and leisure activities also protect against

Alzheimer's and dementia in general (Bennett et al., 2006; Hall et al., 2009; Sattler et al., 2012).

Finally, persistence, intensity, and variety of physical activity are associated with decreased risk of Alzheimer's and vascular dementia, with larger benefits for older people with the APOE  $\epsilon$ 4 gene. In longitudinal research, exercising regularly in midlife predicted reduced late-life dementia, after many other dementia-linked lifestyle factors were controlled (Blondell, Hammersley-Mather, & Veerman, 2014; Smith et al., 2013). Beginning regular exercise in late life is also protective. In one investigation, older adults with mild cognitive impairment and therefore judged to be at risk for Alzheimer's were randomly assigned to either a 24-week home-based physical activity program or to a usual home-care control group (Lautenschlager et al., 2008). At a six-month follow-up, those experiencing the intervention continued to engage in regular exercise and showed slight cognitive improvement, whereas controls had declined in cognitive functioning.

**Helping Alzheimer's Victims and Their Caregivers.** As Ida's Alzheimer's worsened, the doctor prescribed a mild sedative and an antidepressant to help control her behavior. Drugs that increase levels of the neurotransmitters acetylcholine and serotonin show promise in limiting challenging dementia symptoms—especially agitation and disruptiveness, which are particularly stressful for caregivers (National Institute on Aging, 2016). Providing stimulation through engaging activities, exercise, and sensory experiences (touch, music, and videos) also helps reduce inappropriate behaviors (Camp, Cohen-Mansfield, & Capezuti, 2002).

But with no cure available, family interventions ensure the best adjustment possible for the Alzheimer's victim, spouse, and other relatives. Dementia caregivers devote substantially more time to caregiving and experience more stress than do people caring for older adults with physical disabilities (Alzheimer's Association, 2016a). They need assistance and encouragement from extended-family members, friends, and community agencies. The Social Issues: Health box on pages 592–593 describes a variety of helpful interventions for family caregivers. In addition to these strategies, avoiding dramatic changes in living conditions, such as moving to a new location, rearranging furniture, or modifying daily routines, helps people with Alzheimer's disease feel as secure as possible in a cognitive world that is gradually disintegrating.

### LOOK and LISTEN

Investigate formal respite services, providing temporary relief to caregivers of older adults with dementia, in your community. Visit a respite program, and talk to several family caregivers about its impact on the patient's and their own adjustment.

**Vascular Dementia.** In **vascular dementia**, a series of strokes leaves areas of dead brain cells, producing step-by-step degeneration of mental ability, with each step occurring abruptly

after a stroke. Approximately 15 percent of all dementia cases in Western nations are vascular. The disorder affects 1.5 percent of Americans over age 65 (Sullivan & Elias, 2016). At the same time, many victims of Alzheimer's disease also show vascular damage, and in some instances, the two types of dementia are difficult to distinguish.

Vascular dementia is the combined result of genetic and environmental influences. The effects of heredity are indirect, through high blood pressure, cardiovascular disease, and diabetes, each of which increases the risk of stroke. And environmental factors—including cigarette smoking, heavy alcohol use, high salt intake, very low dietary protein, obesity, inactivity, and psychological stress—also heighten stroke risk (Sahathevan, Brodtmann, & Donnan, 2011).

Because of their greater susceptibility to cardiovascular disease, more men than women have vascular dementia. The disease also varies among countries. For example, the occurrence of vascular dementia is particularly high in Japan. Although a low-fat diet reduces Japanese adults' risk of cardiovascular disease, high intake of alcohol and salt and a diet very low in animal protein increase the risk of stroke. As Japanese consumption of alcohol and salt declined and intake of meat rose in recent decades, rates of vascular dementia and stroke-caused deaths dropped (Ikejima et al., 2014; Sekita et al., 2010). However, they remain higher than in other developed nations.

Although Japan presents a unique, contradictory picture (there, cardiovascular disease is low, and stroke is high), in most cases vascular dementia is caused by atherosclerosis. Prevention is the only effective way to stop the disease. The incidence of vascular dementia has dropped in the last two decades, largely as a result of the decline in heart disease and more effective stroke prevention methods (U.S. Department of Health and Human Services, 2015d). Signs that a stroke might be coming are weakness, tingling, or numbness in an arm, a leg, or the face; sudden vision loss or double vision; speech difficulty; and severe dizziness and imbalance. Doctors may prescribe drugs to reduce the tendency of the blood to clot. Once strokes occur, paralysis and loss of speech, vision, coordination, memory, and other mental abilities are common.

**Misdiagnosed and Reversible Dementia.** Careful diagnosis of dementia is crucial because other disorders can be mistaken for it. And some forms of dementia can be treated and a few reversed.

Depression is the disorder most often misdiagnosed as dementia. Between 1 and 5 percent of people over age 65 are severely depressed—a rate lower than for young and middle-aged adults. As we will see in Chapter 18, however, depression rises with age, is often related to physical illness and pain, and can lead to cognitive deterioration. As at younger ages, the support of family members and friends, antidepressant medication, and individual, family, and group therapy can help relieve depression. However, U.S. older adults often do not receive the mental health services they need—partly because Medicare offers reduced coverage for treating mental health problems and partly

HERO IMAGES/GETTY IMAGES

Depression—often related to physical illness and pain—may be misdiagnosed as dementia. With his therapist's support, this older adult has a good chance of avoiding depression during his slow recovery from a shoulder injury.

because doctors rarely refer older people for mental health services (Hinrichsen, 2016; Robinson, 2010). These circumstances increase the chances that depression will deepen and be confused with dementia.

The older we get, the more likely we are to be taking drugs that may have side effects resembling dementia. For example, some medications for coughs, diarrhea, and nausea inhibit the neurotransmitter acetylcholine, leading to Alzheimer's-like symptoms. In addition, some diseases can cause temporary memory loss and mental symptoms, especially among older people, who often become confused and withdrawn when ill (Grande et al., 2016; Tveito et al., 2016). Treating the underlying illness relieves the problem. Finally, environmental changes and social isolation can trigger mental declines (Hawton et al., 2011). When supportive ties are restored, cognitive functioning usually bounces back.

## Health Care

Health-care professionals and lawmakers in industrialized nations worry about the economic consequences of rapid increase in the older population. Rising government-supported health-care costs and demand for certain health-care services, particularly long-term care, are of greatest concern.

**Cost of Health Care for Older Adults.** Adults age 65 and older make up just 14 percent of the U.S. population but account for about one-third of government health-care spending. According to current estimates, the cost of government-sponsored health insurance, or Medicare, for older people will nearly double by 2030 as more baby boomers enter late adulthood and average life expectancy extends further (Centers for Medicare and Medicaid Services, 2016).

Medicare expenses rise steeply with age. People age 75 and older receive, on average, 70 percent more benefits than those who are younger. Most of this increase reflects the need for long-term care—in hospitals and nursing homes—resulting from an

## Social Issues: Health

### Interventions for Caregivers of Older Adults with Dementia

**M**argaret, wife and caregiver of a 71-year-old Alzheimer's patient, sent a desperate plea to an advice columnist at her local newspaper: "My husband can't feed or bathe himself, or speak to anyone or ask for assistance. I must constantly anticipate his needs and try to meet them. Please help me. I'm at the end of my rope."

The effects of Alzheimer's disease are devastating not just to victims but also to family members who provide care with little or no outside assistance. Caregiving under these conditions has been called the "36-hour day" because of its constant demands. Although the majority of family caregivers are middle-aged, an estimated one-third are older adults caring for a spouse or an aging parent. Many are in poor health themselves, yet the number of hours dedicated to caregiving increases with caregiver age and is especially high among ethnic minority older adults, whose cultures emphasize care as a family obligation (Alzheimer's Association, 2016a).

Family members who exceed their caregiving capacities suffer greatly in physical and mental health and are at risk for early mortality (Sörensen & Pinquart, 2005). Severity of cognitive impairments and behavior problems in care recipients are strong predictors of weakening caregiver health (AARP, 2015). And the close relationship between the caregiver and the suffering individual—involving shared

memories, experiences, and emotions—seems to heighten caregiver risk for physical and psychological problems (Monin & Schulz, 2009).

Most communities offer interventions designed to support family caregivers, but they need to be expanded and made more cost-effective. Those that work best address multiple needs: knowledge, coping strategies, caregiving skills, and respite.

#### Knowledge

Virtually all interventions try to enhance knowledge about the disease, caregiving challenges, and available community resources. Knowledge is usually delivered through classes, but websites with wide-ranging information on caregiving, and online communication technologies through which caregivers can obtain and share information, also exist (Czaja, 2016). Gains in knowledge, however, must be combined with other approaches to improve caregivers' well-being.

#### Coping Strategies

Many interventions teach caregivers everyday problem-solving strategies for managing the

dependent person's behavior, along with techniques for dealing with their own negative thoughts and feelings, such as resentment about having to provide constant care. Modes of delivery include support groups, individual therapy, and classes providing coaching in effective coping strategies (Roche, MacCann, & Croot, 2016; Selwood et al., 2007). All yield improvements in caregivers' adjustment and in patients' disturbing behaviors, both immediately and in follow-ups more than a year later.

age-related rise in disabling chronic diseases and acute illnesses. Because Medicare funds only about half of their medical needs, older Americans spend several times as much on health care as their counterparts do in other industrialized nations (OECD, 2015a). And Medicare provides far less support for long-term care than U.S. older people with severe disabilities need.

**Long-Term Care.** When Ida moved into Ruth's home, Ruth promised never to place Ida in an institution. But as Ida's condition worsened and Ruth faced health problems of her own, she couldn't keep her word. Reluctantly, Ruth placed Ida in a nursing home.

Advancing age is strongly associated with use of long-term care services, especially nursing homes. Almost half of U.S. nursing home residents are age 85 and older. Dementia—especially

Alzheimer's disease—most often leads to nursing home placement; frailty is another strong predictor (Harris-Kojetin et al., 2016; Kojima, 2016). Greater use of nursing homes is also prompted by loss of informal caregiving support through widowhood—which mostly affects women—and aging of adult children and other relatives.

Overall, only 3 percent of Americans age 65 and older are institutionalized, less than half the rates in other Western nations, such as Australia, Belgium, the Netherlands, Switzerland, Sweden, and New Zealand, which provide more generous public financing of institutional care (OECD, 2016). Unless nursing home placement follows hospitalization for an acute illness, U.S. older adults must pay for it until their resources are exhausted. At that point, Medicaid (health insurance for the poor) takes

### Caregiving Skills

Caregivers benefit from lessons in how to communicate with older adults who can no longer express thoughts and emotions clearly and handle everyday tasks—for example, sustaining good eye contact to convey interest and caring; speaking slowly, with short, simple words; using gestures to reinforce meaning; waiting patiently for a response; refraining from interrupting, correcting, criticizing, or talking about the older adult as if he or she isn't there; and introducing pleasant activities, such as music and slow-paced children's TV programs, that relieve agitation (Alzheimer's Association, 2016b). Interventions that teach communication skills through active practice reduce patients' troublesome behavior and, as a result, lessen caregivers' distress and boost their sense of self-efficacy (Eggenberger, Heimerl, & Bennett, 2013; Irvine, Ary, & Bourgeois, 2003).

### Respite

Caregivers usually say that *respite*—time away from providing care—is the assistance they most desire. But they may be reluctant to accept friends' and relatives' informal offers to help because of guilt, or to use formal services (such as adult day care or temporary placement in a care facility) because of cost or worries about the older adult's adjustment. Yet respite at least twice a week for several hours improves physical and mental health for most caregivers by enabling them to maintain friendships, engage in enjoyable activities, and sustain a balanced life (Lund et al., 2010b).

For respite to be most effective, caregivers must start using services before they become overwhelmed. Once a rewarding, enjoyable life has been lost, it is difficult to restore. Furthermore, frequent, regular respite is far more helpful than infrequent, irregular use. And planning how best to use respite time is crucial. Caregivers who end up spending respite hours doing housework, shopping, or working usually remain dissatisfied (Lund et al., 2009). Those who engage in activities they had wanted and planned to do gain in psychological well-being.

In addition to time away from the caregiving situation, caregivers benefit from short periods of relief from the unrelenting demands of in-home care. One group of researchers devised a unique tool called Video Respite—a series of videotapes suited to the interests of Alzheimer's patients that provide caregivers with a half-hour to an hour break. On each tape, an actor conducts a slow-paced, simple conversation about familiar experiences, people, and objects, pausing occasionally for the impaired person to respond (Caserta & Lund, 2002). Evaluations show that the videos capture the attention of people with Alzheimer's and reduce problem behaviors, such as wandering, agitation, and aggression.

### Intervention Programs

Multifaceted intervention programs that begin early in the caregiving process, that

continue for many weeks or months, and that are tailored to caregivers' individual needs greatly reduce stress while helping them find satisfactions in caring for a declining loved one. Such interventions usually delay institutional placement of dementia patients as well.

In the Resources for Enhancing Alzheimer's Caregiver Health (REACH) initiative, an array of "active" intervention programs, each including some or all of the ingredients just described, were evaluated against "passive" interventions providing only information and referral to community agencies. Among more than 1,200 participating caregivers, those receiving six months of active intervention declined more in self-reported burden. And one program providing family therapy in the home—through a telephone system facilitating frequent communication among therapist, caregiver, family members, and other support systems—substantially reduced caregiver depressive symptoms (Gitlin et al., 2003; Schultz et al., 2003). Caregivers with greater care responsibility—women versus men, lower-SES versus higher-SES, spouses versus nonspouses—benefited most from active intervention. In additional evaluations, REACH active intervention programs enhanced physical and mental health among caregivers of diverse ethnicities—African American, European American, and Hispanic (Basu, Hochhalter, & Stevens, 2015; Belle et al., 2006; Elliott, Burgio, & DeCoster, 2010).

over. Consequently, the largest users of nursing homes in the United States are people with either very low or high incomes. Middle-income aging adults and their families are more likely to try to protect their savings from being drained by high nursing home costs.

Nursing home use also varies across ethnic groups. For example, European Americans are more likely to be institutionalized than African Americans and Hispanics, who often have large, close-knit extended families with a strong sense of caregiving responsibility. Similarly, Asian and Native-American older adults use nursing homes less often than European Americans (Centers for Medicare and Medicaid Services, 2013; Thomeer, Mudrazija, & Angel, 2014). Overall, families provide at least 60 to 80 percent of all long-term care in Australia,

Canada, New Zealand, the United States, and Western Europe. As we have seen, families of diverse ethnic and SES backgrounds willingly step in to care for older people in times of need.

To reduce institutionalized care of older adults and its associated high cost, experts advocate alternatives, such as publicly funded in-home help for family caregivers (see Chapter 16, page 557). Another option that has increased dramatically over the past two decades is **assisted living**—homelike housing arrangements for older adults who require more help than can be provided at home but less than is usually provided in nursing homes. Assisted living is a cost-effective alternative to nursing homes that prevents unnecessary institutionalization. It also can enhance residents' autonomy, social life, community involvement, and life satisfaction—benefits that we will take up in Chapter 18.

In a nursing home in the Netherlands, a patient enjoys moving landscapes displayed on a screen in an area resembling a train compartment. Institutional care is far less common in the United States than in other Western nations, where public financing is more generous.

In Denmark, the combination of a government-sponsored home-helper system and expansion of assisted-living housing resulted in a substantial reduction in the need for nursing home beds (Hastrup, 2007; Rostgaard, 2012). Strengthening caregiving and health-care services in U.S. assisted-living facilities would result in similarly favorable outcomes, while also enhancing older adults' happiness. The overwhelming majority of residents want to stay in assisted living rather than move to a nursing home.

When nursing home placement is necessary, steps can be taken to improve its quality. For example, the Netherlands has established separate facilities designed to meet the different needs of patients with mental and physical disabilities. And every older person, no matter how disabled, benefits from opportunities to maintain existing strengths and acquire new skills that can compensate for declines. Institutionalized individuals—like aging adults everywhere—desire a sense of personal control, gratifying social relationships, and meaningful and enjoyable daily activities (Alkema, Wilber, & Enguidanos, 2007). As Chapter 18 will reveal, designing nursing homes to meet these needs promotes both physical and psychological well-being.

## Ask yourself

**CONNECT** Explain how each level of ecological systems theory (Chapter 1, pages 23–26) contributes to caregiver well-being and quality of home care for older adults with dementia.

**APPLY** Marissa complained to a counselor that at age 68, her husband, Wendell, no longer initiated sex or cuddled her. Why might Wendell have ceased to interact sexually? What interventions—both medical and educational—could be helpful to Marissa and Wendell?

**REFLECT** What care and living arrangements have been made for older adults needing assistance in your family? How did culture, personal values, financial means, health, and other factors influence those decisions?

## COGNITIVE DEVELOPMENT

**17.9** Describe overall changes in cognitive functioning in late adulthood.

Ruth's complaints to her doctor about difficulties with memory and verbal expression reflect common concerns about cognitive functioning in late adulthood. Decline in speed of processing, under way throughout the adult years, is believed to affect many aspects of cognition in old age. In Chapter 15, we noted that reduced efficiency of thinking contributes to (but may not fully explain) decrements in executive function, especially working-memory capacity and working-memory updating. Declines in inhibition of irrelevant information and impulses, in flexibly shifting between tasks and mental operations, in use of memory strategies, and in retrieval from long-term memory continue in the final decades of life, affecting many aspects of cognitive aging.

Return to Figure 15.7 on page 526, and note that the more a mental ability depends on fluid intelligence (biologically based information-processing skills), the earlier it starts to decline. In contrast, mental abilities that rely on crystallized intelligence (culturally based knowledge) are sustained longer. But maintenance of crystallized intelligence depends on continued opportunities to use and enhance cognitive skills. When these are available, crystallized abilities—vocabulary, general information, and expertise in specific endeavors—can offset losses in fluid intelligence.

Look again at Figure 15.7. In advanced old age, decrements in fluid intelligence limit what people can accomplish even with

LEE SNIDER/ALAMY

These musicians continue to perform in late adulthood, as they have for most of their adult lives, through selective optimization with compensation. They carefully select pieces within range of their current skill, shorten the length of playing sessions to optimize their limited energy, and compensate for reduced playing speed by including just a few well-practiced, rapid passages.

cultural supports, including a rich background of experience, knowledge of how to remember and solve problems, and a stimulating daily life. Consequently, crystallized intelligence shows a modest decline.

Generally, loss outweighs improvement and maintenance as people approach the end of life, but plasticity is still possible: Some individuals display high maintenance and minimal loss at very old ages (Baltes & Smith, 2003; Schaie, 2013). Research reveals greater individual variation in cognitive functioning in late adulthood than at any other time of life (Riediger, Li, & Lindenberger, 2006). Besides fuller expression of genetic and lifestyle influences, increased freedom to pursue self-chosen courses of action—some that enhance and others that undermine cognitive skills—may be responsible.

How can older adults make the most of their cognitive resources? According to one view, those who sustain high levels of functioning engage in **selective optimization with compensation**: Narrowing their goals, they select personally valued activities to optimize (or maximize) returns from their diminishing energy. They also find new ways to compensate for losses (Baltes, Lindenberger, & Staudinger, 2006; Napolitano & Freund, 2016). For example, when famed pianist Arthur Rubinstein was asked at age 80 how he managed to sustain such extraordinary playing, he replied that he was *selective*; he played fewer pieces, carefully choosing those within range of his current skill and stamina. This enabled him to *optimize* his energy; he could practice each piece more. He also devised *compensatory* techniques for a decline in playing speed. For example, before a fast passage, he played extra slowly, so the fast section appeared to his audience to move more quickly.

In late adulthood, personal goals—while still including gains—increasingly focus on maintaining abilities and preventing losses. In one study, researchers asked people to rate their most important physical and cognitive goals for emphasis on growth (“With this goal, I want to improve something or achieve something new”) and maintenance/prevention of losses (“With this goal, I want to maintain something or prevent a loss”) (Ebner, Freund, & Baltes, 2006). As Figure 17.6 shows, compared with young adults, older adults accentuated maintenance and loss prevention.

As we review major changes in memory, language processing, and problem solving, we will consider ways that older adults optimize and compensate in the face of declines. We will also see that certain abilities that depend on extensive life experience, not processing efficiency, are sustained or increase in old age. Last, we take up programs that recognize older people as lifelong learners empowered by new knowledge, just as they were at earlier periods of development.

### LOOK and LISTEN

Interview an older adult about memory and other cognitive challenges, asking for examples. For each instance, invite the older person to describe his or her efforts to optimize cognitive resources and compensate for losses.

**FIGURE 17.6** Personal goal orientation toward growth and maintenance/prevention of loss in young and older adults. Participants were asked to list two physical and two cognitive goals and then to rate each for emphasis on growth and on maintenance or prevention of loss, using an 8-point scale. Older adults—while continuing to pursue growth—placed much greater emphasis on maintenance and loss prevention than did young adults. (From N. C. Ebner, A. M. Freund, & P. B. Baltes, 2006, “Developmental Changes in Personal Goal Orientation from Young to Late Adulthood: From Striving for Gains to Maintenance and Prevention of Losses,” *Psychology and Aging*, 21, p. 671. Adapted by permission of American Psychological Association.)

## Memory

### 17.10 How does memory change in late life?

As older adults take in information more slowly, retain less in working memory, and find it harder to engage in inhibition, apply strategies, and retrieve relevant knowledge from long-term memory, the chances of memory failure increase (Naveh-Benjamin, 2012; Verhaeghen, 2012). Difficulties with *episodic memory*—retrieval of everyday experiences—rise substantially. In comparison, *semantic memory*—general knowledge removed from the context in which it was first learned—is better preserved.

## Explicit versus Implicit Memory

“Ruth, you know that movie we saw—the one with the little 5-year-old boy who did such a wonderful acting job. I’d like to suggest it to Dick and Goldie. But what was it called?” asked Walt.

“I can’t think of it, Walt. We’ve seen a few movies lately. Which theater was it at? Who’d we go with? Tell me more about the little boy—maybe it’ll come to me.”

Although everyone occasionally has memory failures like this, diverse aspects of episodic recall become more challenging in late life. When Ruth and Walt watched the movie, their slower cognitive processing meant that they retained fewer details. And

NIGEL PAVITT/GETTY IMAGES

A grandmother and her granddaughter attend a festival in Sri Lanka. Declines in processing speed and working-memory capacity lead older adults to take in less about a stimulus and its context. As a result, this grandmother may find details of the event difficult to recall.

because their working memories could hold less at once, they attended poorly to *context*—where they saw the movie and who went with them (Zacks & Hasher, 2006). When we try to remember, context serves as an important retrieval cue.

Because older adults take in less about a stimulus and its context, their recall is reduced in relation to that of younger people. For example, they sometimes cannot distinguish an imagined event from one they actually experienced (Rybash & Hruby-Bopp, 2000). They find it harder to recall the source of information, particularly when potential sources are similar—which member of their bridge club made a certain statement, to whom and on which occasion they previously told a certain joke or story, and—in laboratory research—within which of two 10-word lists they had just studied particular words had appeared (Wahlheim & Huff, 2015). Temporal memory—recall of the order in which events occurred or how recently they happened—suffers as well (Hartman & Warren, 2005; Rotblatt et al., 2015).

Older adults' limited working memories increase the likelihood of another type of episodic memory difficulty: They may, for example, travel from the den to the kitchen intending to get something but then not recall what they intended to get. When the context in which they formed the memory intention (the den) differs from the retrieval context (the kitchen), they often experience memory lapses (Verhaeghen, 2012). Once they return to the first context (the den), it serves as a strong cue for their memory

intention because that is where they first encoded it, and they say, “Oh, now I remember why I went to the kitchen!”

A few days later, when Ruth saw a TV ad for the movie whose title she had forgotten, she recognized its name immediately. Recognition—a fairly automatic type of memory that demands little mental effort—suffers less than recall in late adulthood because a multitude of environmental supports for remembering are present. Age-related declines in memory are greatest on **explicit memory** tasks, which require controlled, strategic processing (Hoyer & Verhaeghen, 2006).

Consider another automatic form of memory: **implicit memory**, or memory without conscious awareness. In a typical implicit memory task, you would be shown a list of words, then asked to fill in a word fragment (such as *t—k*). You would probably complete the sequence with a word you had just seen (*task*) rather than another word (*took* or *teak*). Without trying to do so, you would engage in recall.

Age differences in implicit memory are much smaller than in explicit memory. Memory that depends on familiarity rather than on consciously controlled use of strategies is better preserved in old age (Koen & Yonelinas, 2013; Ward, Berry, & Shanks, 2013). This helps explain why semantic memory—recall of vocabulary and general information, which are mostly well-learned and highly familiar—declines far less, and does so at later ages, than recall of everyday experiences (Small et al., 2012). The episodic memory problems aging adults report—for names of people, places where they put important objects, directions for getting from one place to another, and (as we will see) appointments and medication schedules—all place high demands on their more limited working memories and on other executive processes.

## Associative Memory

The memory difficulties just described are part of a general, age-related decline in binding information into complex memories (Smyth & Naveh-Benjamin, 2016). Researchers call this an **associative memory deficit**, or difficulty creating and retrieving links between pieces of information—for example, two items or an item and its context, such as Ruth's attempt to remember the name of the movie with the child actor or where she had seen the movie.

To find out whether older adults have greater difficulty with associative memory than younger adults, researchers show them pairs of unrelated words or pictures of objects (such as *table—overcoat* or *sandwich—radio*) and ask that they study the pairs for an upcoming memory test. During the test, one group of participants is given *single items*, some that had appeared in the study phase and some that had not, and asked to indicate the ones they had studied. The other group is given *item pairs*, some intact from the study phase (*table—overcoat*) and some rearranged (*overcoat—radio*), and asked to indicate which pairs they had studied. As Figure 17.7 illustrates, older adults do almost as well as younger adults on single-item memory tests (Guez & Lev, 2016; Old & Naveh-Benjamin, 2008; Ratcliff & McKoon, 2015).

**FIGURE 17.7** Young and older adults' performance on single-item and item-pair memory tests, supporting an associative memory deficit in late adulthood. After studying pairs of items (in this case, pictures of objects), some participants were asked to identify single items they had seen. Others were asked to identify the item pairs they had seen. Older adults performed almost as well as young adults on the single-item memory test. But they did far worse on the item-pair memory test. (Based on Guez & Lev, 2016.)

But they perform far worse on item-pair tests—findings that support an associative memory deficit.

The memory tasks just described rely on recognition. Older adults perform well when they are required only to recognize single pieces of information. But when researchers complicate recognition tasks by making them depend on associations between unrelated items, older people have difficulty with widely varying associations, including face–name, face–face, word–voice, and person–action pairings (Naveh-Benjamin, 2012). In addition to reduced use of memory strategies, sensory declines make associative memory more challenging. Older adults who see or hear less well must devote extra effort to perceiving information (Naveh-Benjamin & Kilb, 2014). This subtracts from working-memory resources available for processing associations between items.

Easing task demands by providing older adults with helpful memory cues improves their associative memory. For example, to associate names with faces, older people profit from mention of relevant facts about those individuals. And when older adults are directed to use the memory strategy of *elaboration* (relating word pairs by generating a verbal statement or mental image of their relationship), the young–old difference in memory is greatly reduced (Bastin et al., 2013; Naveh-Benjamin, Brav, & Levy, 2007). Clearly, associative deficits are substantially affected by lack of strategy use that helps bind information into integrated wholes.

## Remote Memory

Although older people often say that their **remote memory**, or very long-term episodic recall, is clearer than their memory for recent events, research does not support this conclusion. To inves-

tigate remote recall, researchers probe *autobiographical memory*, or recall of personally meaningful events, such as what you did on your first date or how you celebrated your college graduation. Sometimes participants varying in age are given a series of words (such as *book*, *machine*, *sorry*, *surprised*) and asked to report a personal memory cued by each. Or they may simply be asked to describe important life events, noting the age at which each occurred.

Older adults recall both remote and recent events more often than intermediate events, with recent events mentioned most frequently in word-cue studies. The important-memories method evokes a larger number of remote events because it induces people to search their memories thoroughly for significant experiences (see Figure 17.8). Among remote events recalled, most happened between ages 10 and 30—a period of heightened autobiographical memory called the **remiscence bump** (Janssen, Rubin, & St. Jacques, 2011; Koppel & Berntsen, 2014; Koppel & Rubin, 2016).

The reminiscence bump is evident in the autobiographical recall of older adults from diverse cultures—Bangladesh, China, Japan, Turkey, and the United States (Conway et al., 2005; Demiray, Gülgöz, & Bluck, 2009). Why are adolescent and early adulthood experiences retrieved more readily than those of middle adulthood? Youthful events occur during a period of rapid life change filled with novel experiences that stand out from the humdrum of daily life. Adolescence and early adulthood are also times of identity development, when many personally significant experiences occur. Furthermore, the reminiscence bump characterizes emotionally positive, but not negative, memories. Culturally shared, important life events—school proms, graduations, marriage, birth of children—are usually positive and cluster earlier in life (Dickson, Pillemer, & Bruehl, 2011). In contrast,

**FIGURE 17.8** Distribution of autobiographical memories by reported age at time of the event, using word-cue and important-memories methods. The distributions reflect overall findings of many studies. Most early events recalled occurred between ages 10 and 30, known as the reminiscence bump. The word-cue method evokes a larger number of recent events, the important-memories method a larger number of remote events. (Based on Koppel & Berntsen, 2014.)

negative events—a serious illness, a car accident—are generally unanticipated and are not overrepresented during any life period.

Finally, the richness of older adults' remote autobiographical memories—mentions of people, objects, places, times, feelings, and other details—modestly exceeds that of younger people (Gardner, Mainetti, & Ascoli, 2015). Important early life events are usually recalled many times throughout life, on one's own and in elaborative conversations with others, which strengthen them.

## Prospective Memory

So far, we have considered various aspects of *retrospective memory* (remembrance of things past). **Prospective memory** refers to remembering to engage in planned actions in the future. The amount of mental effort required determines whether older adults have trouble with prospective memory. Because Ruth and Walt knew they were prone to forget appointments, they often asked about them repeatedly. “What time is our dinner engagement, Sybil?” Walt queried several times over the preceding two days. Remembering the dinner date was challenging because Walt typically ate dinner with his daughter on Thursday evenings at 6 p.m., but this time, dinner was set for Tuesday at 7:15 p.m. His questioning was not a sign of dementia. He simply wanted to be sure to keep an important date.

In the laboratory, older adults do better on *event-based* than on *time-based* prospective memory tasks. In an event-based task, an event (such as a certain word appearing on a computer screen) serves as a cue for remembering to do something (pressing a key) while the participant engages in an ongoing activity (reading paragraphs). As long as the event-based task is not complex, older adults do as well as younger adults. But when researchers introduce extra attentional and working-memory demands (for example, press the key when any one of four cues appears), older adults' performance worsens (Kliegel, Jäger, & Phillips, 2008). In time-based tasks, the adult must engage in an action after a certain time interval has elapsed, without any obvious external cue (for example, pressing a key every 10 minutes). Time-based prospective memory requires considerable initiative to keep the planned action in mind and monitor the passage of time while also performing an ongoing activity (Einstein, McDaniel, & Scullin, 2012). Consequently, declines in late adulthood are considerable.

But difficulties with prospective memory seen in the laboratory do not appear in real life, where adults are highly motivated to remember and good at setting up event-based reminders for themselves, such as a buzzer ringing in the kitchen to signal it's time to take medication or a note tacked up prominently displaying the time of a same-day meeting (Schnitzspahn et al., 2011, 2016). In trying to remember a future activity, younger adults rely more on strategies like rehearsal, older adults on external memory aids (Dixon, de Frias, & Bäckman, 2001). In this way, they compensate for their reduced-capacity working memories and the challenge of dividing attention between what they are doing now and what they must do in the future.

Nevertheless, once a prospective memory task is finished, older adults find it harder than younger adults to deactivate, or inhibit, their intention to engage in the future action, especially when cues are still present after the task has been performed. Hence, they sometimes repeat the task again (Scullin et al., 2011). Whereas forgetting whether one has washed one's hair and doing so a second time is harmless, repeating a dose of medication can be dangerous. Older adults benefit from a system of reminders that regularly scheduled tasks have been completed, and they often arrange such systems themselves.

## Language Processing

**17.11** Describe changes in language processing in late adulthood.

Language and memory skills are closely related. In language comprehension (understanding the meaning of spoken or written prose), we recollect what we have heard or read without conscious awareness. Like implicit memory, language comprehension changes little in late life, as long as conversational partners do not speak too quickly and older adults are given enough time to process written text accurately, which enables them to compensate for reduced working-memory capacity. Older readers make a variety of adjustments to ensure comprehension, such as devoting more processing time to new concepts than younger readers do, pausing more often to integrate information, and making good use of story organization to help them recall both main ideas and details. Those who have invested more time in reading and other literacy activities over their lifetimes display faster and more accurate reading comprehension (Payne et al., 2012; Stine-Morrow & Payne, 2016). They benefit from years of greater practice at this highly skilled activity.

Two aspects of language production show age-related losses. The first is retrieving words from long-term memory. When conversing with others, Ruth and Walt sometimes had trouble finding the right words to convey their thoughts—even well-known words they had used many times in the past. Consequently, their speech contained more pronouns and other unclear references than it did at younger ages. They also spoke more slowly and paused more often, partly because they needed time to search their memories for certain words (Kemper, 2015). And compared to younger people, they more often reported a *tip-of-the-tongue state*—certainty that they knew a word accompanied by an inability to produce it.

Second, planning what to say and how to say it in everyday conversation is harder in late adulthood. As a result, Walt and Ruth displayed slightly more hesitations, false starts, word repetitions, and sentence fragments as they aged. Their statements were also less grammatically complex and less well-organized than before (Kemper, 2016).

What explains these changes? Whereas the meanings older people want to convey have many “mental connections” with

In Alberta, Canada, a First Nations older adult speaks out against environmental destruction caused by the oil industry. To compensate for language-production problems, older people speak more slowly and use simplified grammatical structures. However, they tend to be better storytellers than younger people.

other meanings, the sound of a word has only one mental connection to the word's underlying concept. Consequently, as associative memory declines with age, memory difficulties in everyday conversation are especially apparent in word retrieval (Burke & Shafto, 2004). Also, diminished working-memory capacity is involved. Because less information can be held at once, older adults have difficulty coordinating the multiple tasks required to produce complex, coherent speech.

As with memory, older adults develop compensatory techniques for their language production problems. For example, they speak more slowly so they can devote more effort to retrieving words and organizing their thoughts. Sacrificing efficiency for greater clarity, they use more sentences, but shorter ones, to convey their message (Griffin & Spieler, 2006). As older people monitor their word-retrieval failures and try hard to overcome them, they more often resolve tip-of-the-tongue states than younger people do (Schwartz & Frazier, 2005).

Most aspects of language production, including its content, grammatical correctness, and pragmatics (social appropriateness), are unaffected by aging. And aging adults are advantaged in narrative competence. In telling a story, they draw on their extensive life experience, constructing elaborate, hierarchically organized episodes with rich information about a main character's goals, actions, and motivations and with summarizing

references to the story's contemporary significance (Kemper et al., 1990). As a result, listeners tend to prefer older adults' stories to those of young people.

Nevertheless, when conversational partners detect an older person's slowed speech and shorter, at times fragmented sentences, negative stereotypes of aging often lead them to engage in *elderspeak*—a form of communication resembling infant-directed speech, consisting of a limited vocabulary, simplified expressions, and high-pitched, exaggerated expression. Lacking coherence and connectives between sentences, this distorted way of speaking actually impairs aging adults' comprehension and conversational engagement. Furthermore, older people readily detect the patronizing undertone of elderspeak (Williams et al., 2008). Even those who are cognitively impaired and in nursing homes react by withdrawing or expressing anger.

## Problem Solving

### 17.12 How does problem solving change in late life?

Problem solving is another cognitive skill that illustrates how aging brings not only declines but also adaptive changes. Problem solving in the laboratory, where tasks have goals set by the researcher, declines in late adulthood (Finucane et al., 2005). Older adults' memory limitations make it hard to keep all relevant facts in mind when dealing with a complex hypothetical problem. For similar reasons, financial decision making—evaluating loan and investment options—tends to be less effective than it was in midlife (see page 530 in Chapter 15).

Yet the everyday problems older adults encounter differ from hypothetical problems devised by researchers—and also from everyday problems experienced at earlier ages. After retirement, older adults do not have to deal with workplace problems. Their children are typically grown and living on their own, and their marriages have endured long enough to have fewer difficulties. With age, major concerns involve dealing with extended-family relationships (for example, expectations of adult children that they babysit grandchildren) and managing IADLs, such as preparing nutritious meals, paying bills, and attending to health concerns.

How do older people solve problems of daily living? Their strategies extend the adaptive problem solving of midlife. As long as they perceive problems as under their control and as important, they are active and effective in solving them (Berg & Strough, 2011). Older adults generate a smaller number of strategies compared to young and middle-aged adults, perhaps because they include only strategies they have previously found helpful, based on their long life experience (Strough et al., 2008). At the same time, older adults are particularly good at adapting strategies to fit problem conditions—home, relatives, and friends (Skinner, Berg, & Uchino, 2014). And because they are especially concerned with maintaining positive relationships, as we

will see in Chapter 18, they usually do what they can to avoid interpersonal conflicts.

The health arena illustrates the adaptiveness of everyday problem solving in late life. Older adults make faster decisions about whether they are ill, seek medical care sooner, and select treatments more quickly. In contrast, young and middle-aged adults are more likely to adopt a “wait and see” approach in favor of gathering more facts, even when a health problem is serious (Meyer, Russo, & Talbot, 1995). This swift response of older people is interesting in view of their slower cognitive processing. Research reveals that they have accumulated more health-related knowledge, which enables them to move ahead with greater certainty (Meyer, Talbot, & Ranalli, 2007). Acting decisively when faced with health risks is sensible in old age.

Finally, older adults report that they often consult others—generally spouses and adult children, but also friends, neighbors, and members of their religious congregation—for advice about everyday problems (Strough et al., 2003). And compared with younger married couples, older couples more often collaborate in problem solving, and researchers judge their jointly generated strategies as highly effective—even on demanding tasks that require complex memory and reasoning (Peter-Wight & Martin, 2011; Rauters et al., 2011). In jointly solving problems, older people seem to compensate for moments of cognitive difficulty, yielding enhanced performance.

## Wisdom

**17.13** What capacities make up wisdom, and how is it affected by age and life experience?

We have seen that a wealth of life experience enhances the storytelling and problem solving of older adults. It also underlies another capacity believed to reach its height in old age: **wisdom**. When researchers ask people to describe wisdom, most mention breadth and depth of practical knowledge, ability to reflect on and apply that knowledge in ways that make life more bearable and worthwhile; emotional maturity, including the ability to listen patiently and empathetically and give sound advice; and the altruistic form of creativity discussed in Chapter 15 that involves contributing to humanity and enriching others' lives. One group of researchers summed up the multiple cognitive and personality traits that make up wisdom as “expertise in the conduct and meaning of life” (Baltes & Smith, 2008; Baltes & Staudinger, 2000, p. 124; Kunzmann, 2016).

During her college years, Ruth and Walt's granddaughter Marci telephoned with a pressing personal dilemma. Ruth's advice reflected the features of wisdom just mentioned. After her boyfriend Ken moved to another city to attend medical school, Marci, unsure whether her love for Ken would endure, had begun dating another student. “I can't stand being pulled in two direc-

tions,” she exclaimed. “I'm thinking of calling Ken and telling him about Steve.”

“This is not a good time, Marci,” Ruth advised. “You'll break Ken's heart before you've had a chance to size up your feelings for Steve. And you said Ken's taking some important exams in two weeks. If you tell him now and he's distraught, it could affect the rest of his life.”

Wisdom—whether applied to personal problems or to community, national, and international concerns—requires the “pinnacle of insight into the human condition” (Baltes & Staudinger, 2000; Birren, 2009). Not surprisingly, cultures around the world assume that age and wisdom go together. In village and tribal societies, the most important social positions, such as chieftain and shaman (religious leader), are reserved for the old. Similarly, in industrialized nations, older adults are chief executive officers of large corporations, high-level religious leaders, members of legislatures, and supreme court justices. What explains this widespread trend? According to an evolutionary view, the genetic program of our species grants health, fitness, and strength to the young. Culture tames this youthful advantage in physical power with the insights of the old (Csikszentmihalyi & Nakamura, 2005). As wise older adults identify useful knowledge and reflections to transmit to younger people, they ensure balance and interdependence between generations.

In the most extensive research to date on development of wisdom, adults ranging in age from 20 to 89 responded to

JUERGEN FRANK/CORBIS VIA GETTY IMAGES

British-born neurologist Oliver Sacks died in 2015 at age 82. Through his work with patients suffering from neurological disorders, Sacks exemplified the cognitive, reflective, and emotional qualities that make up wisdom. “In examining disease,” Sacks wrote, “we gain wisdom about anatomy and physiology and biology. In examining the person with disease, we gain wisdom about life.”

uncertain real-life situations—for example, what to consider and do if a good friend is about to commit suicide or if, after reflecting on your life, you discover that you have not achieved your goals (Staudinger, 2008; Staudinger, Dörner, & Mickler, 2005). Responses were rated for five ingredients of wisdom:

- Knowledge about fundamental concerns of life, including human nature, social relations, and emotions
- Effective strategies for applying that knowledge to making life decisions, handling conflict, and giving advice
- A view of people that considers the multiple demands of their life contexts
- A concern with ultimate human values, such as the common good, as well as respect for individual differences in values
- Awareness and management of the uncertainties of life—that many problems have no perfect solution

Results revealed that age is no guarantee of wisdom. A small number of adults of diverse ages ranked among the wise. But type of life experience made a difference. People in human-service careers who had extensive training and practice in grappling with human problems tended to attain high wisdom scores. Other high-scorers held leadership positions (Staudinger, 1996; Staudinger & Glück, 2011). And when age and relevant life experiences were considered together, more older than younger people scored in the top 20 percent.

In addition to age and life experience, having faced and overcome adversity appears to be an important contributor to late-life wisdom (Ardelt & Ferrari, 2015). In one study, low- and moderate-income older adults nominated by aging-services providers as wise reported deriving valuable life lessons from coping with hardships, including patience, perseverance, forgiveness, and willingness to accept advice and support from others (Choi & Landeros, 2011). One participant, who in her thirties had lost her husband to cancer, became a single parent of four children, and worked for low wages as a nurse's aid while earning a college degree in nursing, said, "It was hard. . . . I had a lot of help from my classmates. . . . When I became a nurse, I already understood what pain was, and this made me better able to relate to my patients. You have got to have empathy and be able to listen when people suffer from pain and guilt" (p. 606).

Compared to their age-mates, older adults with the cognitive, reflective, and emotional (compassionate) qualities that make up wisdom are better educated, forge more positive relations with others, and score higher on the personality dimension of openness to experience (Kramer, 2003). Wisdom is also linked to personal growth (continued desire to expand as a person), sense of autonomy and purpose in life (enabling resistance to social pressures to think and act in certain ways), generativity, and favorable adjustment to aging (Ardelt & Ferrari, 2015; Wink & Staudinger, 2016). Wise older people seem to flourish, even when faced with physical and cognitive challenges. This suggests that finding ways to promote wisdom would be a powerful means of both contributing to human welfare and fostering a gratifying old age.

## Factors Related to Cognitive Maintenance and Change

**17.14** Cite factors related to cognitive maintenance and change in late adulthood.

Heritability research suggests a modest genetic contribution to individual differences in cognitive change in late adulthood (Deary et al., 2012). At the same time, as in middle adulthood, a mentally active life is vital for preserving cognitive resources. Above-average education; frequent contact with family members and friends; stimulating work, leisure pursuits, and community participation; and a flexible personality predict higher mental test scores and reduced cognitive decline into advanced old age (Schaie, 2013; Wang et al., 2013). Today's aging adults in industrialized nations are better educated than any previous generation. As more baby boomers enter late adulthood, this trend is expected to continue, forecasting improved preservation of cognitive functions.

As noted earlier, health status powerfully predicts older adults' cognitive functioning. In longitudinal research, cigarette smokers declined cognitively at a faster rate than their nonsmoking counterparts, as did overweight and obese people, even after initial health status, SES, and mental test performance were controlled (Dahl et al., 2010; Smith et al., 2013). And a wide variety of chronic conditions, including cardiovascular disease, diabetes, osteoporosis, and arthritis, are strongly associated with cognitive declines (O'Connor & Kraft, 2013). But we must be cautious in interpreting this link between physical and cognitive deterioration. The relationship may be exaggerated by the fact that brighter adults are more likely to engage in health-protective behaviors, which postpone the onset of serious disease.

As people grow older, their cognitive scores show larger fluctuations from one occasion to the next. This rising instability of performance—especially in speed of response—accelerates in the seventies and is associated with cognitive declines, along with neurobiological signs of shrinkage in the prefrontal cortex and deficient brain functioning (Bielak et al., 2010; Lövdén et al., 2012; MacDonald, Li, & Bäckman, 2009). It seems to signal end-of-life brain degeneration.

In the year before Walt died, those close to him noticed that he had become less active and more withdrawn, even in the company of friends. **Terminal decline** refers to acceleration in deterioration of cognitive functioning prior to death. Some investigations indicate that it is limited to a few aspects of intelligence, others that it occurs generally, across many abilities. Findings also differ greatly in its estimated length—from 1 to 3 to as long as 14 years, with an average of 4 to 5 years (Lövdén et al., 2005; MacDonald, Hultsch, & Dixon, 2011; Rabbitt, Lunn, & Wong, 2008). In several studies, a sharp drop in psychological well-being, including diminished sense of personal control and social participation and increased negative affect, predicted mortality

(Gerstorf & Ram, 2013; Schilling, Wahl, & Wiegering, 2013). The downturn is especially steep in people age 85 and older and is only weakly related to mental deterioration or chronic illnesses.

Perhaps different kinds of terminal decline exist—one type arising from disease processes, another reflecting general biological breakdown due to normal aging. What we do know is that an accelerating falloff in cognitive performance or in emotional investment in life is a sign of loss of vitality and impending death.

## Cognitive Interventions

**17.15** Discuss outcomes of interventions aimed at helping older adults sustain cognitive skills.

For most of late adulthood, cognitive declines are gradual. Although aging of the brain contributes to them, recall from our earlier discussion that the brain can compensate by growing new neural fibers and recruiting additional regions to support cognitive functions. Furthermore, some cognitive decrements may be due to disuse of particular skills rather than biological aging. If plasticity of development is possible, then interventions that train older people in cognitive strategies should at least partially reverse the age-related declines we have discussed.

Older adults' relatively well-preserved *metacognition* is a powerful asset in training efforts. Most, for example, are aware of memory declines, report troublesome anxiety when faced with demanding memory situations, and know they must take extra steps to ensure recall of important information (Blake & Castel, 2016). Their impressive metacognitive understanding is also evident in the wide-ranging techniques they devise to compensate for everyday cognitive challenges.

The Adult Development and Enrichment Project (ADEPT) is the most extensive cognitive intervention program conducted to date (Schaie, 2005). By using participants in the Seattle Longitudinal Study (see Chapter 15, pages 524–525), researchers were able to do what no other investigation has done: assess the effects of cognitive training on long-term development.

Intervention began with adults over age 64, some of whom had maintained their scores on tests of two mental abilities (inductive reasoning and spatial orientation) over the previous 14 years and others who had shown declines. After just five one-hour training sessions in one of two types of mental test items, two-thirds of participants improved their performance on the trained skill. Gains for decliners were dramatic: Forty percent returned to the level at which they had been functioning 14 years earlier! A follow-up after 7 years revealed that although scores dropped somewhat, participants remained advantaged in their trained skill over age-mates trained in the other ability. Finally, “booster” training at this time led to further gains, although these were smaller than the earlier gains.

In another large-scale intervention study called ACTIVE (Advanced Cognitive Training for Independent and Vital

Elderly), more than 2,800 65- to 84-year-olds were randomly assigned to a 10-session training program focusing on one of three abilities—speed of processing, memory strategies, or reasoning—or to a no-intervention control group. Again, trained older adults showed an immediate advantage in the trained skill over controls that was still evident—though smaller in magnitude—at a 5-year follow-up and, for speed and reasoning, at a 10-year follow-up. Furthermore, 5 and 10 years after intervention, cognitive training was associated with reduced declines in ability to perform IADLs—outcomes strongest for the speed-of-processing group and, secondarily, the reasoning group (Rebok et al., 2014; Wolinsky et al., 2006). Speed gains also predicted other aspects of everyday functioning, including more favorable self-rated health, reduced depressive symptoms, fewer at-fault motor vehicle collisions, and longer time to giving up driving (Tennstedt & Unverzagt, 2013). The investigators speculated that speed-of-processing training induces a broad pattern of brain activation, affecting many regions.

Clearly, many cognitive skills can be enhanced in old age. Small-scale studies targeting executive function that provide intensive training over multiple weeks show promising improvements, especially on working-memory tasks. In some research, gains lasted for several months following intervention and transferred to other cognitive skills, such as sustained attention and episodic memory (Brehmer, Westerberg, & Bäckman, 2012; Grönholm-Nyman, 2015). A vital goal is to shift intervention from the laboratory to the community, weaving it into aging adults' recurring experiences. Community programs in the participatory arts—including dance, music, and theater training—yield gains on a broad range of cognitive measures (Noice, Noice, & Kramer, 2014). Refer to the Social Issues: Education box on the following page for a “dramatic” illustration.

Extending the focus of training to include beliefs that promote sustained effort may be helpful. Targeting self-efficacy in training programs by emphasizing late-life cognitive potential boosts both self-efficacy and cognitive gains in older people (West, Bagwell, & Dark-Freudeman, 2008). Furthermore, working in groups may offer unique opportunities for strengthening self-efficacy (“If they can do it, so can I”) along with social support for persisting (Hastings & West, 2009). As we will see in the next section, another promising approach is to provide older adults with well-designed, highly stimulating educational experiences in which cognitive training in socially rich contexts is an integral part.

## Lifelong Learning

**17.16** Discuss types of continuing education and benefits of such programs in late life.

The competencies aging adults need to live in our complex, changing world are the same ones younger people need: communicating effectively through spoken and written systems; locating

## Social Issues: Education

### The Art of Acting Enhances Cognitive Functioning in Older Adults

Actors face a daunting task: They must memorize massive quantities of dialogue and then reproduce it accurately and spontaneously, as if they genuinely mean what they say. No wonder the most common question asked of actors is, “How did you learn all those lines?”

Interviews with professional actors reveal that most don’t memorize lines as many people assume—by rote, or rehearsing the lines many times. Instead, they focus on the meaning of the words. First, they analyze the script for the character’s intentions, breaking it down into what they call “beats”—small, goal-directed chunks of dialogue. Then they represent the role as a sequence of goals, one leading to the next. When actors recall this chain of goals, lines become easier to remember (Noice & Noice, 2006; Noice, Noice, & Kramer, 2014). For example, one actor divided a half-page of dialogue into three beats: “to put [the other character] at ease,” “to start a conversation with him,” “to flatter/draw him out.”

To create a beat sequence, actors engage in extensive elaboration of dialogue segments. For example, to the line, “Perhaps he’s in love with me but doesn’t know it,” an actor might create a visual image of an uncertain lover, relate the material to a past love affair of her own, and match her own mood to the feeling tone of the statement. Deep elaborative processing of the dialogue segment, along with analysis of its beat goal, yields verbatim recall without rote memorization.

information, sorting through it, and selecting what is needed; using math strategies, such as estimation; planning and organizing activities, including making good use of time and resources; mastering new technologies; and understanding past and current events and the relevance of each to their own lives. Older people also need to acquire new, problem-centered coping strategies—ways to sustain health and operate their households efficiently and safely—and updated vocational skills, for those who continue to work.

Participation by people age 65 and older in continuing education has increased substantially over the past few decades.

Actors’ script learning is so successful that on stage, they are free to “live in the moment,” focusing on communicating authentic meaning through action, emotion, and utterance while speaking verbatim lines. This intermodal integration of spoken word with facial expression, tone of voice, and body language contributes further to script retention.

Can aging adults benefit from exercises that teach the essence of acting—thorough mastery of a script, enabling complete immersion in performance? In a series of studies, several hundred adults, diverse in SES and ranging in age from their sixties to nineties, were randomly assigned to either theater-arts training, singing lessons, or no-intervention control groups. The theater-arts training consisted of twice-weekly group sessions over a month’s time in which participants engaged in cognitively demanding acting exercises: They analyzed the goals of brief scenes so they could become fully engrossed in acting out their meaning, and were explicitly instructed not to memorize the script by rote repetition (Noice & Noice, 2006, 2013; Noice, Noice, & Staines, 2004). Compared with singing-lesson and wait-list controls, theater-training participants showed greater gains on tests of working-memory

PHOTO: DUNCAN BURNHAM. PICTURED L TO R - LARRY EGGAN, WES WETTON, LYNDA STRAW, NORMA OBERHOLTZ (YOUNG AT HEARTLAND) FROM A SCENE WRITTEN BY LINDA STRAW, “FREE-FLYING DINO,” SUMMER SHOWCASE 2016. WITH PERMISSION OF HEARTLAND THEATRE COMPANY.

These community-theater actors master their lines by focusing on the meaning of a character’s words in goal-directed chunks. Teaching these script-learning techniques to aging adults results in diverse cognitive benefits that persist for at least several months after intervention ends.

capacity, word and prose recall, verbal fluency, problem solving, and IADLs. In a follow-up, cognitive improvements were still evident four months after the intervention ended.

The theater training required highly effortful intermodal processing, which may explain its cognitive benefits. fMRI research indicates that deeply processing verbal meanings strongly activates certain areas in the frontal lobes of the cerebral cortex in aging adults, yielding levels of neural activity close to those of younger people (Park, 2002). These findings lend neurobiological support to the power of acting, with its challenging intermodal processing of meaning, to enhance human memory.

Successful programs include a wide variety of offerings responsive to the diversity of older people and teaching methods suited to their developmental needs.

### Types of Programs

One summer, Walt and Ruth attended a Road Scholar program at a nearby university. After moving into a dormitory room, they joined 30 others for two weeks of morning classes on Shakespeare, afternoon visits to points of interest, and evening performances of plays at a nearby Shakespeare festival.

## Applying what we Know

### Increasing the Effectiveness of Educational Experiences for Older Adults

TECHNIQUE	DESCRIPTION
Provide a positive learning environment.	Many older adults have internalized negative stereotypes of their own abilities and come to the learning environment with low self-efficacy. A supportive group atmosphere helps convince them that they can learn.
Allow ample time to learn new information.	Rate of learning varies widely among older adults. Presenting information over multiple sessions or allowing for self-paced instruction aids mastery.
Present information in a well-organized fashion.	Older adults do not organize information as effectively as younger adults. Material that is outlined, presented, and then summarized enhances memory and understanding. Digressions make a presentation harder to comprehend.
Relate information to older adults' knowledge and experiences.	Relating new material to what older adults have already learned, by drawing on their extensive knowledge and experiences and giving many vivid examples, enhances recall.
Adapt the learning environment to fit changes in sensory systems.	Adequate lighting, availability of large-print reading materials, appropriate sound amplification, reduced background noise, and clear, well-organized visual aids to supplement verbal teaching ease information processing.

In its most recently reported year, Road Scholar campus-based programs, and their recent extension to travel experiences around the world, attracted more than 100,000 American and Canadian older adults. Some programs make use of community resources through classes on local ecology or folk life. Others focus on innovative topics and experiences—writing one's own life story, discussing contemporary films with screenwriters, whitewater rafting, Chinese painting and calligraphy, or acquiring French language skills. Travel programs are enriched by in-depth lectures and expert-led field trips.

Similar educational programs have sprung up in the United States and elsewhere. The Bernard Osher Foundation collaborates with more than 120 U.S. universities to establish Osher Lifelong Learning Institutes on campuses. Each offers older adults a wide array of stimulating learning experiences, from auditing regular courses, to forming learning communities that address common interests, to helping to solve community problems. Originating in France, the University of the Third Age<sup>2</sup> provides Western European, British, and Australian older people with university- and community-sponsored courses, workshops on special topics, and excursions, with older adults often doing the teaching.

### LOOK and LISTEN

Find out if your college or university hosts a lifelong learning program, and attend an on-campus session. What did you observe about older adults' capacity for complex learning?

Participants in the programs just mentioned tend to be active, well-educated, and financially well-off. Much less is available for older people with little education and limited income. Community senior centers with inexpensive offerings related to everyday living attract more low-SES people than programs such as Road Scholar or Universities of the Third Age (Formosa, 2014). Regardless of course content and which older adults attend, using the techniques summarized in Applying What We Know above increases the effectiveness of educational experiences.

<sup>2</sup>The term *Third Age*, as we will see in Chapter 18, refers to the period after the "Second Age" of midlife, when older people are freed from responsibilities of earning a living and rearing children to focus on personal fulfillment.

PHOTO BY CARL STUDINA/ROAD SCHOLAR

Active, adventurous older adults explore the sights, sounds, streets, and monuments of Dublin's authors, poets, and playwrights as part of a Road Scholar travel program to Ireland.

## Benefits of Continuing Education

Older participants in continuing education report a rich array of benefits—understanding new ideas in many disciplines, learning new skills that enrich their lives, making new friends, and developing a broader perspective on the world (Preece & Finsen, 2007). Furthermore, participants come to see themselves differently. Many abandon their own ingrained negative stereotypes of aging when they realize that adults in late life—including themselves—can still engage in complex learning.

Older adults' willingness to acquire new knowledge and skills is apparent in the recent, rapid rise in their use of computers and the Internet. They are now the fastest growing age group to embrace online technology as they discover its many practical benefits, including assistance with shopping, banking, health-care management, and communication. Currently, about 60 percent of adults age 65 and older access the Internet, with the majority of these going online on a daily basis. As noted on page 559 in Chapter 16, 35 percent of aging adults are users of social media sites, primarily Facebook (Charness & Boot, 2016; Perrin, 2015). Still, older people have joined the computer and Internet community to a lesser extent than younger people. Those who are less well-educated and have lower incomes, and those over age 75, are especially reluctant, with many perceiving the technology as too complicated—an attitude that continuing education

can overcome (Smith, 2014). With patient training, support, and modified equipment and software to suit their physical and cognitive needs, older adults readily enter the online world, often becoming nearly as devoted and skilled as younger users.

The educational needs of aging adults are likely to be given greater attention in coming decades, as their numbers grow and they assert their right to lifelong learning. Once this happens, false stereotypes—“they are too old to learn” or “education is for the young”—are likely to weaken and, perhaps, disappear.

## Ask yourself

**CONNECT** Describe cognitive functions that are maintained or that improve in late adulthood. What aspects of aging contribute to them?

**APPLY** Estelle complained that she had recently forgotten two of her regular biweekly hair appointments and sometimes had trouble finding the right words to convey her thoughts. What cognitive changes account for Estelle's difficulties? What can she do to compensate?

**REFLECT** Interview an older adult in your family, asking about ways the individual engages in selective optimization with compensation to make the most of declining cognitive resources. Describe several examples.

## Summary / chapter 17

### PHYSICAL DEVELOPMENT

#### Life Expectancy (p. 570)

**17.1** *Distinguish between chronological age and functional age, and discuss changes in life expectancy since the beginning of the twentieth century.*

- People age biologically at different rates, making chronological age an imperfect indicator of **functional age**. Dramatic gains in **average life expectancy** confirm that biological aging can be modified by environmental factors, including improved nutrition, medical treatment, sanitation, and safety.
- Length of life and, especially, **average healthy life expectancy** can be predicted by a country's health care, housing, and social services, along with lifestyle factors. In developing nations, both are shortened by poverty, malnutrition, disease, and armed conflict.

- With advancing age, the gender gap in average life expectancy declines, as do differences between European Americans and African Americans.

EPA EUROPEAN PRESS PHOTO AGENCY B.V./ALAMY

- Longevity runs in families, but environmental factors become increasingly important after age 75 to 80. Scientists disagree on whether **maximum lifespan** can be extended beyond 122 years—the oldest verified age.

#### Physical Changes (p. 573)

**17.2** *Describe physical declines of late adulthood, and changes in the nervous and sensory systems.*

- With age, growing numbers of older adults experience physical declines, evident in difficulties carrying out **activities of daily living (ADLs)**, or basic self-care tasks, and **instrumental activities of daily living (IADLs)**, which are necessary to conduct the business of daily life.
- Neuron loss occurs throughout the cerebral cortex, with greater shrinkage in the frontal lobes, especially the prefrontal cortex, and the corpus callosum. The cerebellum and the hippocampus also lose neurons. The brain compensates by forming new synapses and, to a limited degree, generating new neurons. The autonomic nervous system functions less well and releases more stress hormones.

- Older adults tend to suffer from impaired vision and may experience **cataracts** and **macular degeneration**. Hearing impairments are more common than visual impairments, with decline in speech perception having the greatest impact on life satisfaction.

GARY CONNOR/PHOTOEDIT

- Taste and odor sensitivity wane, making food less appealing. Touch sensitivity also deteriorates, particularly on the fingertips.

### 17.3 Describe cardiovascular, respiratory, and immune system changes and sleep difficulties in late adulthood.

- Reduced capacity of the cardiovascular and respiratory systems becomes more apparent in late adulthood, especially in lifelong smokers and in people who have not reduced dietary fat or who have had extensive exposure to environmental pollutants. Exercise can slow cardiovascular aging and facilitate respiratory functioning.
- The immune system functions less effectively in late life, permitting diseases to progress and making **autoimmune responses** and stress-induced infection more likely.
- Older adults find it harder to fall asleep, stay asleep, and sleep deeply. Until age 70 or 80, men have more trouble sleeping than women because of prostate enlargement (initiating frequent urination) and **sleep apnea**.

### 17.4 Describe changes in physical appearance and mobility in late adulthood, along with effective adaptations to these changes.

- Outward signs of aging—white hair, wrinkled and sagging skin, age spots, and decreased height and weight—become more noticeable. Mobility diminishes as muscle and bone strength and joint flexibility decline.
- Wanting to be younger (as opposed to feeling younger) than one's actual age is associated with less positive well-being. High sense of personal control, which is linked to problem-centered coping strategies, yields improved physical functioning.
- Assistive technology** helps older people cope with physical declines, sustaining an effective person–environment fit that enhances psychological well-being.

- Negative stereotypes of aging have a stressful, disorganizing impact on older adults' functioning, whereas positive stereotypes reduce stress and foster physical and mental competence.

## Health, Fitness, and Disability

(p. 581)

### 17.5 Discuss health and fitness in late life, paying special attention to nutrition, exercise, and sexuality.

- Most older adults rate their health favorably and have a high sense of self-efficacy about protecting it. Low-SES ethnic minority older people remain at greater risk for certain health problems, are less trusting of health-care providers, and are less likely to believe they can control their health.
- In late life, men continue to be more prone to fatal diseases and women to disabling conditions. In industrialized nations, **compression of morbidity** has occurred, largely as a result of medical advances and improved socioeconomic conditions; further gains will depend on reducing negative lifestyle factors. In the developing world, comprehensive strategies are needed.
- Risk of dietary deficiencies increases in late life, but except for calcium and vitamin D, a daily vitamin–mineral supplement is recommended only for those suffering from malnutrition. Exercise, even when begun in late adulthood, is a powerful health intervention.
- Though sexual activity declines, especially among women, most married older adults report continued, regular sexual enjoyment.

JONATHAN KIRBY/GETTY IMAGES

### 17.6 Discuss physical disabilities associated with late adulthood.

- Illness and disability increase toward the end of life. Heart disease and cancer are the leading causes of death, followed by respiratory diseases. **Primary aging** contributes to **frailty** in the elderly, but **secondary aging** (declines due to hereditary defects and negative environmental influences) plays a larger role.

- Osteoarthritis** and **rheumatoid arthritis** are widespread among older adults, especially women. Type 2 diabetes also increases.
- The death rate from unintentional injuries reaches an all-time high from age 65 on, largely due to motor vehicle collisions and falls. Visual declines and slowed reaction time often contribute.

### 17.7 Discuss mental disabilities associated with late adulthood.

- Alzheimer's disease**, the most common form of **dementia**, often starts with severe memory problems. It brings personality changes, depression, disintegration of purposeful movements, loss of ability to comprehend and produce speech, and death. Underlying these changes are abundant **neurofibrillary tangles** and **amyloid plaques** and lowered neurotransmitter levels in the brain.
- Familial Alzheimer's, related to genes involved in generation of harmful amyloid, generally has an early onset and progresses rapidly. About half of sporadic Alzheimer's victims have an abnormal gene that results in insulin deficiency linked to brain damage.
- Diverse environmental factors, including a high-fat diet, physical inactivity, overweight and obesity, smoking, chronic depression, cardiovascular disease, stroke, diabetes, and head injuries increase the risk of Alzheimer's. A "Mediterranean diet," education, and an active lifestyle are associated with lower incidence. Better-educated people may develop a **cognitive reserve** that increases the aging brain's tolerance to injury.
- Heredity contributes to **vascular dementia** indirectly, through high blood pressure, cardiovascular disease, and diabetes. Because of their greater susceptibility to cardiovascular disease, more men than women are affected.
- Treatable problems, such as depression, side effects of medication, and reactions to social isolation, can be mistaken for dementia.

### 17.8 Discuss health-care issues that affect older adults.

- Only a small percentage of older Americans are institutionalized, less than half the rates in other Western nations with more generous public financing of institutional care. Though ethnic differences exist, family members provide most long-term care in Western nations. Publicly funded in-home help and **assisted living** can reduce the high costs of institutional placement and increase older adults' life satisfaction.

## COGNITIVE DEVELOPMENT

### 17.9 Describe overall changes in cognitive functioning in late adulthood. (p. 594)

- Individual differences in cognitive functioning are greater in late adulthood than at any other time of life. Older adults can make the most of their cognitive resources through **selective optimization with compensation**. Personal goals increasingly emphasize maintaining abilities and preventing loss.

### Memory (p. 595)

#### 17.10 How does memory change in late life?

- Memory failure increases with age, especially on **explicit memory** tasks, which require controlled, strategic processing. Recall of context, source, and temporal order of episodic events declines. Automatic forms of memory, such as recognition and **implicit memory**, suffer less. In general, an **associative memory deficit** characterizes older adults' memory difficulties.
- Contrary to what older people often report, **remote memory** is not clearer than recent memory. Remote memory is best for events that occurred between ages 10 and 30, a period of heightened autobiographical recall called the **reminiscence bump**.
- In the laboratory, older adults do better on event-based than on time-based **prospective memory** tasks. In everyday life, they compensate for declines in prospective memory by using external memory aids.

### Language Processing (p. 598)

#### 17.11 Describe changes in language processing in late adulthood.

- Language comprehension changes little in late life. Age-related losses occur in two aspects of language production: retrieving words from long-term memory and planning what to say and how

to say it in everyday conversation. Older people compensate by speaking more slowly and using shorter sentences. Aging adults are advantaged in narrative competence.

ASHLEY COOPER/ALAMY

### Problem Solving (p. 599)

#### 17.12 How does problem solving change in late life?

- Hypothetical problem solving declines in late adulthood. In everyday problem solving, older adults are effective as long as they perceive problems as under their control and as important. Older people make faster decisions about health than younger people and often consult others about everyday problems.

### Wisdom (p. 600)

#### 17.13 What capacities make up wisdom, and how is it affected by age and life experience?

- Wisdom** involves extensive practical knowledge, ability to reflect on and apply that knowledge in ways that make life more bearable and worthwhile, emotional maturity, and altruistic creativity. When age and relevant life experience are combined, more older than younger people rank among the wise. Having faced and overcome adversity appears to contribute to late-life wisdom.

### Factors Related to Cognitive Maintenance and Change (p. 601)

#### 17.14 Cite factors related to cognitive maintenance and change in late adulthood.

- Healthy, mentally active people are likely to maintain their cognitive abilities into advanced old age. A wide array of chronic health conditions are associated with cognitive declines.
- With age, older adults' cognitive scores become increasingly unstable. As death approaches, **terminal decline** often occurs.

### Cognitive Interventions (p. 602)

#### 17.15 Discuss outcomes of interventions aimed at helping older adults sustain cognitive skills.

- Training in cognitive skills can offer large, persisting benefits for older people who have experienced cognitive declines. Targeting self-efficacy enhances cognitive gains.

### Lifelong Learning (p. 602)

#### 17.16 Discuss types of continuing education and benefits of such programs in late life.

- Increasing numbers of older people continue their education through university courses, community offerings, and other programs. Participants acquire new knowledge and skills, new friends, a broader perspective on the world, and an image of themselves as more competent. Unfortunately, fewer continuing-education opportunities are available to low-SES older adults.

#### **Successful Aging**

With Ruth at his side, Walt spoke to the guests at their sixtieth-anniversary party. “Even when things were hard,” he reflected, “the time of life I liked best always seemed to be the current one. When I was a kid, I adored playing baseball. In my twenties, I loved learning the photography business. And of course,” Walt continued, glancing affectionately at Ruth, “our wedding was the most memorable day of all.”

He went on: “We never had much money for luxuries, but we found ways to have fun anyway—singing in the church choir and acting in community theater. And then Sybil was born. It meant so much to me to be a father—and now a grandfather and a great-grandfather. Looking back at my parents and grandparents and forward at Sybil, Marci, and Marci’s son Jamel, I feel a sense of unity with past and future generations.” With a smile, Walt added, “We keep up with Marci and Jamel through Facebook and Twitter!”

Walt and Ruth greeted old age with calm acceptance, grateful for the gift of long life and loved ones. Yet not all older adults find such peace of mind. Walt’s brother Dick was contentious, complaining about petty issues and major disappointments alike: “Goldie, why’d you serve cheesecake? No one eats cheesecake on birthdays!” “Know why we’ve got financial worries? Uncle Louie wouldn’t lend me the money to keep the bakery going, so I *had* to retire.”

A mix of gains and losses characterizes these twilight years, extending the multidirectionality of development begun early in life. On one hand, old age is usually a time of pleasure and tranquility, when children are grown, life’s work is nearly done, and responsibilities are lightened. On the other hand, it brings concerns about declining physical functions, unwelcome loneliness, and the growing specter of imminent death.

In this chapter, we consider how older adults reconcile these opposing forces. Although some are weary and discontented, most traverse this period with poise and calm composure. They attach deeper significance to life and reap great benefits from family and friendship bonds, leisure activities, and community involvement. We will see how personal attributes and life history combine with home, neighborhood, community, and societal conditions to mold emotional and social development in late life. ●

## Erikson's Theory: Ego Integrity versus Despair

**18.1** According to Erikson, how does personality change in late adulthood?

The final psychological conflict of Erikson's (1950) theory, **ego integrity versus despair**, involves coming to terms with one's life. Adults who arrive at a sense of integrity feel whole, complete, and satisfied with their achievements. They have adapted to the mix of triumphs and disappointments that are an inevitable part of love relationships, child rearing, work, friendships, and community participation. They realize that the paths they followed, abandoned, and never selected were necessary for fashioning a meaningful life course.

The capacity to view one's life in the larger context of all humanity—as the chance combination of one person and one segment in history—contributes to the serenity and contentment that accompany integrity. “These last few decades have been the happiest,” Walt murmured, clasping Ruth's hand—only weeks before the heart attack that would end his life. At peace with himself, his wife, and his children, Walt had accepted his life course as something that had to be the way it was.

In a study that followed a sample of women diverse in SES throughout adulthood, midlife generativity predicted ego integrity in late adulthood. Ego integrity, in turn, was associated with more favorable psychological well-being—a more upbeat mood, greater self-acceptance, higher marital satisfaction, closer rela-

tionships with adult children, greater community involvement, and increased ease in accepting help from others when it is needed (James & Zarrett, 2007). As Erikson's theory indicates, psychosocial maturity in late life brings increased contentment, affectionate, enjoyable bonds with others, and continued service to society.

Scanning the newspaper, Walt pondered, “I keep reading these percentages: One out of five people will get heart disease, one out of three will get cancer. But the truth is, one out of one will die. We are all mortal and must accept this fate.” The year before, Walt had given his granddaughter, Marci, his collection of prized photos, which had absorbed him for over half a century. With the realization that the integrity of one's own life is part of an extended chain of human existence, Erikson suggested, death loses its sting (Vaillant, 2002, 2012). In support of this view, older adults who report having attained intrinsic (personally gratifying) life goals typically express acceptance of their own death (Van Hiel & Vansteenkiste, 2009). Those who emphasize attainment of extrinsic goals (such as money or prestige) more often fear life's end.

The negative outcome of this stage, despair, occurs when aging adults feel they have made many wrong decisions, yet time is too short to find an alternate route to integrity. Without another chance, the despairing person finds it hard to accept that death is near and is overwhelmed with bitterness, defeat, and hopelessness. According to Erikson, these attitudes are often expressed as anger and contempt for others, which disguise contempt for oneself. Dick's argumentative, fault-finding behavior, tendency to blame others for his personal failures, and regretful view of his own life reflect this deep sense of despair.

Erik Erikson and his wife Joan exemplified the ideal of Erikson's final stage. They aged gracefully, felt satisfied with their achievements, and were often seen together, contented and deeply in love.

## Other Theories of Psychosocial Development in Late Adulthood

**18.2** Discuss Robert Peck's and Joan Erikson's views of psychosocial development in late adulthood, along with implications of the positivity effect and reminiscence for older adults' lives.

As with Erikson's stages of early and middle adulthood, other theorists have clarified and refined his vision of late adulthood, specifying the tasks, thought processes, and behaviors that contribute to aging adults' sense of ego integrity and psychological well-being.

### Peck's Tasks of Ego Integrity and Joan Erikson's Gerotranscendence

According to Robert Peck (1968), attaining ego integrity involves three distinct tasks:

- *Ego differentiation*: For those who invested heavily in their careers, finding other ways to affirm self-worth—through family, friendship, and community life

- *Body transcendence*: Surmounting physical limitations by emphasizing the compensating rewards of cognitive, emotional, and social powers
- *Ego transcendence*: As contemporaries die, facing the reality of death constructively through efforts to make life more secure, meaningful, and gratifying for younger generations

In Peck's theory, ego integrity requires older adults to move beyond their life's work, their bodies, and their separate identities by investing in a future that extends beyond their own life-span. Research suggests that as people grow older, both *body transcendence* (focusing on psychological strengths) and *ego transcendence* (orienting toward a better life for those who will follow) increase. In a study of women, those in their eighties and nineties stated with greater certainty than those in their sixties that they "accept the changes brought about by aging," "have moved beyond fear of death," "have a clearer sense of the meaning of life," and "have found new, positive spiritual gifts to explore" (Brown & Lowis, 2003).

Erikson's widow Joan Erikson suggested that these attainments actually represent development beyond ego integrity (which requires satisfaction with one's past life) to an additional psychosocial stage that she calls **gerotranscendence**—a cosmic and transcendent perspective directed beyond the self to affinity with past and future generations and oneness with the universe. Drawing on her own experience of aging, her observations of her husband's final years, and the work of others, Joan Erikson speculated that success in attaining gerotranscendence is apparent in heightened inner calm and contentment and additional time spent in quiet reflection (Erikson, 1998; Tornstam, 2000, 2011).

But more research is needed to confirm the existence of a distinct, transcendent late-life stage. Beyond getting older, major negative life events, such as declines in health or financial difficulties, are associated with reports of cosmic, gerotranscendent reflections. This suggests that inner contemplation is one means older adults use to adapt to stressful, unchangeable circumstances (Read et al., 2014). Furthermore, besides focusing intently on life's meaning, many of the very old continue to be invested in the real world—strengthening bonds with intimate partners and friends, keeping up with current events, and engaging in leisure, volunteer, and career pursuits. One participant in Vaillant's (2012) longitudinal investigation of college men (see page 477 in Chapter 14), reinterviewed in his mid-eighties, reported recently marrying his long-time partner and regularly giving paid public lectures in his field. In response to Vaillant's telephone call, he remarked that Vaillant was fortunate to have reached him on his day off!

## The Positivity Effect

In Chapter 13, we discussed research on development of adults' reasoning about emotion (see page 458). Recall that cognitive-affective complexity (awareness and coordination of positive and negative feelings into an organized self-description) increases from adolescence through middle adulthood and then declines as basic information-processing skills diminish in late adulthood.

SEAN SPRAGUE / ROBERT HARDING

In Lijiang, China, an aging adult joins her daughter in watching a street performer. Older people selectively attend to emotionally positive over negative information, which contributes to their remarkable resilience.

But older people display a compensating emotional strength, called the **positivity effect**: Compared with younger people, they selectively attend to and better recall emotionally positive over negative information (Hilimire et al., 2014; Mather & Carstensen, 2005). This bias toward the emotionally positive, also evident in more rapid ERP brain waves in response to emotionally positive than negative stimuli, contributes to older adults' remarkable resilience. Despite physical declines, increased health problems, a restricted future, and death of loved ones, most older adults maintain a sense of optimism, gaining in enjoyment, happiness, and general psychological well-being with age (Carstensen et al., 2011; Murray & Isaacowitz, 2016).

What explains this late-life rise in positivity? According to one view, aging adults' wealth of life experiences has enabled them to become expert in emotional self-regulation (Blanchard-Fields, 2007). For example, in describing interpersonal conflicts, older adults, compared with younger people, more often report using constructive strategies, such as expressing affection or disengaging to let the situation blow over, that prevent lasting negative affect (Birditt & Fingerman, 2005; Charles et al., 2009; Luong, Charles, & Fingerman, 2011). And when they cannot avoid negative experiences, older people are especially effective at emotion-centered coping (controlling distress internally). In one study, patients ranging in age from the late twenties to the late eighties, who were recently diagnosed with colon cancer, completed measures of emotion regulation. Those age 60 and older, compared to their younger counterparts, appraised the situation as less threatening and as more of a positive challenge (Hart & Charles, 2013). These more adaptive interpretations predicted more rapid reduction in distress over the following 18 months.

In addition to greater competence at regulating emotion, awareness of less time left to live motivates older adults to accentuate positive affect (Schiebe & Carstensen, 2010). A shortened time perspective induces people to focus on gratifying,

meaningful experiences in the present—a finding we will return to later in this chapter.

Of course, circumstances do occur in which older people cannot take advantage of their strengths in regulating emotion. Cognitive declines or chronic stressors can overwhelm their capacity to manage negative experiences (Charles & Carstensen, 2014; Charles & Luong, 2013). And as noted in Chapter 17, when intense, persistent stress arises, it is more taxing for older adults: Age-related changes in cardiovascular and endocrine system functioning lead blood pressure and cortisol levels to remain elevated for longer periods, with negative consequences for both physical and mental health that heighten stress further.

Nevertheless, the positivity effect is a significant late-life psychosocial attainment. Much research confirms that high levels of emotional stability and well-being are the norm rather than the exception among older people, at least into their seventies or early eighties.

## Reminiscence

We often think of older adults as engaged in **reminiscence**—telling stories about people and events from their past and reporting associated thoughts and feelings. Indeed, the widespread image of a reminiscing older person ranks among negative stereotypes of aging. In this common view, older people live in the past to escape the realities of a shortened future and the nearness of death. Yet research reveals no age differences in total quantity of reminiscing! Rather, younger and older adults often use reminiscence for different purposes (Westerhof, Bohlmeijer, & Webster, 2010). And certain types of reminiscence are positive and adaptive.

In his comments on major events in his life at the beginning of this chapter, Walt was engaging in a form of reminiscence called *life review*—calling up past experiences with the goal of achieving greater self-understanding. According to Robert Butler (1968), most older adults engage in life review as part of attaining ego integrity—a notion that has led many therapists to encourage life-review reminiscence. Older adults who participate in counselor-led life-review interventions, aimed at integrating positive and negative memories from all life periods, report increased self-esteem, greater sense of purpose in life, and reduced depression (Latorre et al., 2015; O’Rourke, Cappeliez, & Claxton, 2011). Life-review interventions can also help bereaved adults find a place for lost loved ones in their emotional lives, reinvest energy in other relationships, and move on with life (Worden, 2009).

Although life review occurs more often among older than younger adults, many older people who are high in self-acceptance and life satisfaction spend little time evaluating their past (Wink, 2007). In several studies in which older adults were asked what they considered to be the best time of life, 10 to 30 percent identified one of the decades of late adulthood. Early and middle adulthood received especially high marks, whereas childhood and adolescence ranked as less satisfying (Field, 1997; Mehlsion, Platz, & Fromholt, 2003). These findings challenge the widespread belief that aging adults inevitably focus on the past

and wish to be young again. To the contrary, contemporary older people in industrialized nations are largely present- and future-oriented: They seek avenues for personal growth and fulfillment (see the Cultural Influences box on the next page).

Clearly, life review is not essential for adapting well to late adulthood. Indeed, reminiscence that is *self-focused*, engaged in to reduce boredom and revive bitter events, is linked to adjustment problems. Compared with younger people, older adults less often engage in this ruminative form of reminiscence, and those who do are often anxious and depressed from dwelling on painful past experiences (O’Rourke, Cappeliez, & Claxton, 2011). Life-review therapy, aimed at helping them focus on positive memories, improves psychological well-being (Lamers et al., 2015; Pinquart & Forstmeier, 2012).

In contrast, extroverted people favor *other-focused* reminiscence directed at social goals, such as solidifying family and friendship ties and reliving relationships with lost loved ones. And at times, older adults—especially those who score high in openness to experience—engage in *knowledge-based* reminiscence, drawing on their past for effective problem-solving strategies and for teaching younger people. These socially engaged, mentally stimulating forms of reminiscence help make life rich and rewarding (Cappeliez, Rivard, & Guindon, 2007). Perhaps because of their strong storytelling traditions, African-American and Chinese immigrant older adults are more likely than their European-American counterparts to use reminiscence to teach others about the past (Shellman, Ennis, & Bailey-Addison, 2011; Webster, 2002).

For young and old alike, reminiscence often occurs during times of life transition. Older adults who have recently retired, been widowed, or moved to a new residence may turn temporarily to the past to sustain a sense of personal continuity (Westerhof & Bohlmeijer, 2014). As long as they do not get stuck in mulling over unresolved difficulties, reminiscence probably helps them recapture a sense of meaning.

## Stability and Change in Self-Concept and Personality

**18.3** Cite stable and changing aspects of self-concept and personality, and discuss spirituality and religiosity in late adulthood.

Longitudinal research reveals continuing stability of the “big five” personality traits from mid- to late life (see Chapter 16, page 548). Yet the ingredients of ego integrity—wholeness, contentment, and image of the self as part of a larger world order—are reflected in several significant late-life changes in both self-concept and personality.

## Secure and Multifaceted Self-Concept

Older adults have accumulated a lifetime of self-knowledge, leading to more secure, multifaceted conceptions of themselves than at earlier ages (Diehl et al., 2011). Ruth, for example, knew

## Cultural Influences

### The New Old Age

After retiring, pediatrician Jack McConnell tried a relaxing lifestyle near a lake and golf course, but it worked poorly for the energetic 64-year-old. As his desire for a more fulfilling retirement grew, he noticed that outside his comfortable, gated neighborhood were many people serving community needs as gardeners, laborers, fast-food workers, and the like, yet who lived in or near poverty. The contrast galvanized Jack to found *Volunteers in Medicine*, a free clinic for working-poor adults and their families who lack health insurance (Croker, 2007). Five years later, at age 69, Jack was overseeing a highly cost-effective operation involving 200 retired doctors, nurses, and lay volunteers, who treat 6,000 patients a year.

Jack exemplifies a revised approach to late adulthood, one infused with new cultural meanings: Increasingly, older adults are using their freedom from work and parenting responsibilities to pursue personally enriching interests and goals. In doing so, they are giving back to their communities in significant ways, serving as role models for younger generations, and strengthening their sense of ego integrity with images of themselves as living ethical, worthy lives.

Added years of longevity and health plus financial stability have granted this active, opportunistic time of life to so many contemporary older adults that some experts believe a new phase of late adulthood has evolved called the **Third Age**—a term originating over a decade ago in France that spread through Western Europe and recently has stretched to North America. According to this view, the First Age is childhood, the Second Age is the adult period of earning a living and rearing children, and the Third Age—extending from ages 65 to 79, and sometimes longer—is a time of personal fulfillment (Gilleard &

Higgs, 2011). The Fourth Age brings physical decline and need for care.

The baby boomers—healthier and financially better off than any preceding aging generation—are moving into the latter decades of their lives with expectations of continued aspirations and accomplishment. This has helped define the Third Age as a time of self-realization and high life satisfaction.

But even people a decade or two ahead of the oldest baby boomers are experiencing the Third Age as a phase of new goal setting and purpose rather than as an extended vacation in anticipation of decline (Winter et al., 2007). As we will see later in this chapter, retirement is no longer a one-way, age-graded event. Instead, many older adults are building hybrid lives—leaving career jobs to work at different jobs that utilize their skills and that they experience as more meaningful than the work they left. Consider Lucille Shulklapper, who as a child dreamed of becoming a writer but, after marrying, became a teacher while rearing three children. Retiring in her late fifties, Lucille published six books of poetry and fiction and, at age 80, her first children's book. "I am living beyond my dreams," she reflected (Ellin, 2015, p. B5).

Although policy makers often express concern about the huge, impending baby-boomer burden on Social Security and Medicare, this large pool of vigorous, publicly minded future aging adults has the potential to make enormous economic and social contributions. Today's Third Agers donate billions to the global economy in volunteer work, continue to participate in the work force in large numbers, make creative contributions, and

RYAN STONE/THE NEW YORK TIMES/REDUX

Lucille Shulklapper grew up dreaming of becoming a writer, a goal she finally attained at age 60, after retiring from her teaching career. Over the next two decades, she published six poetry and fiction books and, at age 80, her first children's book.

give generously to their families through monetary support and other forms of help—far more than they receive (see page 631).

But as midlife roles shrink and terminate, too few alternatives are available for the many older people eager to make a difference (Bass, 2011). Societies need to provide abundant volunteer, national service, and other public interest opportunities, thereby harnessing their rich older adult resources to solve pressing problems. The U.S. Senior Corps, which offers expanded service incentives and options to adults age 55 and older—tutoring children, teaching English to immigrants, assisting victims of disasters, and engaging with their communities in many other ways—is a major step in that direction.

Finally, although the majority of U.S. adults in their sixties and seventies have more energy and choice than ever before, others—more often women and ethnic minorities—suffer from financial hardship and distress and have little chance for new beginnings (Cubanski, Casillas, & Damico, 2015). When social security, health care, and housing policies ensure a comfortable Third Age to all older adults, benefits accrue to the entire nation.

with certainty that she was independent, well-organized, empathetic, and good at budgeting money, counseling others, giving dinner parties, and figuring out who could be trusted and who couldn't. Furthermore, when young and older adults were asked for several life-defining memories, 65- to 85-year-olds were

more likely to mention events with a common theme—such as the importance of relationships or personal independence—and to explain how the events were interrelated (McLean, 2008). Their autobiographical selves emphasized coherence and consistency, despite physical, cognitive, and occupational changes. As

Ruth remarked humorously, “I know who I am. I’ve had plenty of time to figure it out!”

The firmness and multifaceted nature of Ruth’s self-concept enabled her to compensate for lack of skill in domains she had never tried, had not mastered, or could no longer perform as well as before. Consequently, it allowed for self-acceptance—a key feature of integrity. In a study of old (70 to 84 years) and very old (85 to 103 years) Germans asked to respond to the question “Who am I?,” participants mentioned a broad spectrum of life domains, including hobbies, interests, social participation, family, health, and personality traits. Adults in both age groups expressed more positive than negative self-evaluations (Freund & Smith, 1999). Positive, multifaceted self-definitions predicted psychological well-being.

As the future shortens, most older adults, into their eighties and nineties, continue to mention—and actively pursue—hoped-for selves in the areas of physical health, cognitive functioning, personal characteristics, relationships, social responsibility, and leisure (Frazier, 2002; Markus & Herzog, 1991). With respect to feared selves, physical health is even more prominent than it was in midlife.

At the same time, possible selves reorganize well into old age. When the German 70- to 103-year-olds just mentioned were followed longitudinally for four years, the majority deleted some possible selves and replaced them with new ones (Smith & Freund, 2002). Although future expectations become more modest and concrete with age (“taking a daily thirty-minute walk” rather than “getting in better shape”), older adults usually take steps to attain their goals. Engaging in hope-related activities, in turn, is associated with gains in life satisfaction and with longer life (Brown, 2016b; Hoppmann et al., 2007). Clearly, late adulthood is not a time of withdrawal from future planning!

## Agreeableness, Acceptance of Change, and Openness to Experience

During late adulthood, shifts occur in personality characteristics that, once again, defy aging stereotypes. Old age is not a time in which the personality inevitably becomes rigid and morale declines. Rather, a flexible, optimistic approach to life, which fosters resilience in the face of adversity, is common.

Longitudinal research reveals that older adults gain modestly in *agreeableness* into their seventies, becoming more generous, acquiescent, and good-natured. However, declines in agreeableness tend to occur after age 80 as more people face physical and cognitive challenges (Allemand, Zimprich, & Martin, 2008; Môtus, Johnson, & Deary, 2012; Weiss et al., 2005; Wortman, Lucas, & Donnellan, 2012). Agreeableness seems to characterize healthy aging adults who accentuate the positive, despite life’s imperfections.

At the same time, older adults show age-related dips in *extroversion*, perhaps reflecting a narrowing of social contacts as people become more selective about relationships—a trend we will take up in a later section. Older people also tend to decline in *openness to experience*, likely due to awareness of cognitive

changes (Allemand, Zimprich, & Martin, 2008; Donnellan & Lucas, 2008). But engaging in cognitively challenging activities can promote openness to experience! In one study, 60- to 94-year-olds participated in a 16-week cognitive training program in reasoning, which included experience in solving challenging but enjoyable puzzles. During the program, the trained group showed steady gains in both reasoning and openness to experience not displayed by untrained controls. Sustained intellectual engagement seemed to induce older adults to view themselves as more open (Jackson et al., 2012). Openness, in turn, predicts pursuit of intellectual stimulation, thereby contributing to enhanced cognitive functioning.

Another late-life development is greater *acceptance of change*—an attribute older adults frequently mention as important to psychological well-being (Rossen, Knafel, & Flood, 2008). When asked about dissatisfactions in their lives, many say they are not unhappy about anything! Acceptance of change is also evident in most older people’s effective coping with the loss of loved ones. The capacity to accept life’s twists and turns, many of which are beyond one’s control, is vital for adaptive functioning in late adulthood.

Most aging adults are resilient, bouncing back in the face of adversity—especially if they did so earlier in their lives. And their generally positive outlook contributes to their resilience by protecting them from stress and enabling them to conserve physical and mental resources needed for effective coping (Ong, Mroczek, & Riffin, 2011). The minority who are high in neuroticism—emotionally negative, short-tempered, and dissatisfied—tend to cope poorly with stressful events and are at risk for health problems and earlier death (Mroczek, Spiro, & Turiano, 2009).

## Spirituality and Religiosity

How do older adults manage to accept declines and losses yet still feel whole, complete, and calmly composed in the face of a shrinking future? One possibility, consistent with Erikson’s and Peck’s emphasis on a transcendent perspective in late adulthood, is the development of a more mature sense of spirituality—an inspirational sense of life’s meaning. But for many people, religion provides beliefs, symbols, and rituals that guide this quest for meaning.

Older adults attach great value to religious beliefs and behaviors. In a recent survey of a large, nationally representative sample of Americans, 65 percent of those age 65 and older said that religion is very important in their lives, and nearly half reported attending religious services at least once a week—the highest of any age group (Pew Research Center, 2016c). Similar cross-sectional trends exist in countries as diverse as Belize, Germany, India, Russia, and Togo (Deaton, 2009). Although health and transportation difficulties reduce organized religious participation in advanced old age, older people generally become more religious or spiritual as they age.

The late-life increase in religiosity, however, is usually modest, and it is not universal. Longitudinal research reveals that

many people show stability in religiosity throughout adulthood, while others follow diverse paths of change—gaining or declining to varying degrees (Ai, Wink, & Ardel, 2010; Kashdan & Nezleck, 2012; Krause & Hayward, 2016; Wang et al., 2014). For example, in a British investigation following adults for two decades, one-fourth of older adults said they had become less religious, with some citing disappointment at the support they had received from their religious institution during stressful times (such as bereavement) as the reason (Coleman, Ivani-Chalian, & Robinson, 2004).

Despite these variations, spirituality and faith may advance to a higher level in late adulthood—away from prescribed beliefs toward a more reflective approach that emphasizes links to others and is at ease with mystery and uncertainty. According to James Fowler’s theory of faith development, mature adults develop new faith capacities, including awareness of their own belief system as just one of many possible worldviews, contemplation of the deeper significance of religious symbols and rituals, openness to other religious perspectives as sources of inspiration, and (especially in late life) an enlarged vision of a common good that serves the needs of all humanity (Fowler & Dell, 2006). For example, as a complement to his Catholicism, Walt became intensely interested in Buddhism, especially its focus on attaining perfect peace and happiness by mastering thoughts and feelings, never harming others, and resisting attachment to worldly objects.

Involvement in both organized and informal religious activities is especially high among low-SES ethnic minority older people, including African-American, Hispanic, and Native-American groups. In African-American communities, churches not only provide contexts for deriving meaning from life but also are centers for education, health, social welfare, and political activities aimed at improving life conditions. Aging African Americans look to religion as a powerful resource for social support beyond the family and for the inner strength to withstand daily stresses and physical impairments (Armstrong & Crowther, 2002). Compared with their European-American agemates, more African-American older adults report feeling closer to God and engaging in prayer as a means of overcoming life’s problems (Krause & Hayward, 2016).

As at earlier ages, in late adulthood women are more likely than men to say that religion is very important to them, to participate in religious activities, and to engage in a personal quest for connectedness with a higher power (Pew Research Center, 2016c; Wang et al., 2014). Women’s higher rates of poverty, widowhood, and participation in caregiving, including caring for chronically ill family members, expose them to higher levels of stress and anxiety. As with ethnic minorities, they turn to religion for social support and for a larger vision of community that places life’s challenges in perspective.

Religious involvement is associated with diverse benefits, including better physical and psychological well-being, more time devoted to exercising and leisure activities, increased sense of closeness to family and friends, greater generativity (care for others), and deeper sense of meaning (or purpose) in

HILL STREET STUDIOS/GETTY IMAGES

This aging parishioner seeks counsel from his church minister. For many people in late adulthood, religiosity strengthens their capacity to cope with life’s hardships, reducing distress and enhancing quality of life.

life (Boswell, Kahana, & Dilworth-Anderson, 2006; Krause, 2012; Krause et al., 2013; Wink, 2006, 2007). In longitudinal research, both organized and informal religious participation predicted longer survival, after family background, health, social, and psychological factors known to affect mortality were controlled (Helm et al., 2000; Sullivan, 2010).

But aspects of religion that make a difference in aging adults’ lives are not always clear. In some research, religious *activity*—not religious belief or membership in a congregation—was associated with declines in distress following negative life events, such as loss of a spouse or a life-threatening illness (Kidwai et al., 2014; Lund, Caserta, & Dimond, 1993). Increased social engagement and social support brought about by religious participation were believed to be responsible. Other evidence, however, indicates that among religious older people, belief in God’s powers strengthens during late adulthood and contributes substantially to reduced distress and higher self-esteem, optimism, and life satisfaction, especially among low-SES, ethnic minorities (Hayward & Krause, 2013b; Schieman, Bierman, & Ellison, 2010, 2013). Their personal relationship with God seems to help them cope with life’s hardships.

## Contextual Influences on Psychological Well-Being

**18.4** Discuss the influence of control versus dependency, physical health, negative life changes, and social support on older adults’ psychological well-being.

As we have seen in this and the previous chapter, most adults adapt well to old age, yet some feel dependent, incompetent, and worthless. Personal and situational factors combine to affect aging adults’ psychological well-being. Identifying these contextual influences is vital for designing interventions that foster positive adjustment.

## Control versus Dependency

As Ruth's eyesight, hearing, and mobility declined in her eighties, Sybil visited daily to help with self-care and household tasks. During the hours mother and daughter were together, Sybil interacted most often with Ruth when she asked for help with activities of daily living. When Ruth handled tasks on her own, Sybil usually withdrew.

Observations of people interacting with older adults in both private homes and institutions reveal two highly predictable, complementary behavior patterns. In the first, called the **dependency-support script**, dependent behaviors are attended to immediately. In the second, the **independence-ignore script**, independent behaviors are mostly ignored. Notice how these sequences reinforce dependent behavior at the expense of independent behavior, regardless of the older person's competencies (Baltes, 1995, 1996). Even a self-reliant individual like Ruth did not always resist Sybil's unnecessary help because it brought about social contact.

Among older people who experience no difficulty with daily activities, opportunities to interact with others are related to high satisfaction with everyday life. In contrast, among aging adults who have trouble performing daily activities, social contact is frequently associated with a less positive everyday existence (Lang & Baltes, 1997). This suggests that social interaction while assisting older people with physical care, household chores, and errands is often not meaningful and rewarding but, rather, demeaning and unpleasant. Older adults' negative reactions to caregiving can result in persisting depression (Newsom & Schulz, 1998). But whether assistance from others undermines well-being depends on many factors, including the social and cultural context in which helping occurs, the quality of help offered, and the caregiver-older adult relationship.

Why do family members and other caregivers often respond in ways that promote excessive dependency in old age? Stereotypes of older people as passive and incompetent appear to be responsible. After reading passages that activated these stereotypes (by portraying aging adults as inept), older people responded with more frequent help-seeking behavior (Coudin & Alexopoulos, 2010).

In Western societies, which highly value independence, many older adults fear relinquishing control and becoming dependent on others. This is especially so for those with a high need for self-determination (Curtiss, Hayslip, & Dolan, 2007). As physical and cognitive limitations rise, granting older adults the freedom to choose those activities in which they desire help preserves their autonomy (Lachman, Neupert, & Agrigoroaei, 2011). In this way, they can conserve their strength by investing it in self-chosen, highly valued activities, using a set of strategies considered in Chapter 17: *selective optimization with compensation*.

Much research confirms that feelings of personal control diminish in late life (Kandler et al., 2015; Lachman, Neupert, & Agrigoroaei, 2011). But retaining as much control as they can helps older adults protect their well-being for as long as possible. In a longitudinal study of a nationally representative sample of

1,600 German adults, those who expressed a high sense of control (being able to determine most of what happens to them) reported greater life satisfaction during the three years prior to their death (Gerstorf et al., 2014). Yet typically, well-being drops sharply during the final few years.

Think about the varied ways aging adults optimize their functioning while compensating for declines. Notice how they adaptively modify their personal goals: They invest in goals that enable them to remain active and self-determining, adjust those goals to suit their changing capacities, and disengage from goals that overextend their capacities, turning toward other, attainable goals (Heckhausen, Wrosch, & Schultz, 2010). In doing so, older people strive to remain active agents in the direction of their own lives. When family and caregiving environments support their efforts, most aging adults are resilient, sustaining a sense of optimism, self-efficacy, purpose, and investment in overcoming obstacles until very late in life.

Assistance aimed at enabling older adults to use their capacities fully in pursuit of their goals creates an effective **person-environment fit**—a good match between their abilities and the demands of their living environments, which promotes adaptive behavior and psychological well-being (Fry & Debats, 2010). When people cannot maximize use of their capacities (have become excessively dependent), they react with boredom and passivity. When they encounter environmental demands that are too great (receive too little assistance), they experience overwhelming stress.

© JANE SHAUCK PHOTOGRAPHY/ALAMY

By letting her son help with grocery shopping, will this Mexican 80-year-old become too dependent? Not necessarily. When older adults assume personal control over areas of dependency, they can conserve their strength for highly valued activities.

## Physical Health

As noted in Chapter 16, physical health is a powerful predictor of psychological well-being. Physical declines and chronic disease are among the strongest risk factors for late-life depression (Whitbourne & Meeks, 2011). Although fewer older than young and middle-aged adults are depressed (see Chapter 17), profound feelings of hopelessness rise with age as physical disability leads to diminished personal control and increased social isolation. But more than actual physical limitations, *perceived negative physical health* predicts depressive symptoms (Verhaak et al., 2014; Weinberger & Whitbourne, 2010). This helps explain the stronger physical impairment–depression relationship among higher-SES aging adults (Schieman & Plickert, 2007). Because of their lifetime of better physical health, they may experience physical limitations as more unexpected and challenging.

The relationship between physical and mental health problems can become a vicious cycle, each intensifying the other. In survey research conducted in 15 countries, adults of all ages reported that mental health problems actually interfered more than physical disabilities with activities of daily living, including home management and social life (Ormel et al., 2008). At times, dependency and “giving up” trigger rapid physical decline in a sick aging adult. This downward spiral can be hastened by a move to a nursing home, yielding reduced control over daily life and greater distance from family and friends. In the months after admission, many residents judge their quality of life to have worsened substantially, become severely anxious and depressed, and deteriorate rapidly. The stress of illness together with institutionalization is associated with escalating physical and mental health problems and with mortality (Miu & Chan, 2011; Scocco, Rapattoni, & Fantoni, 2006).

Depression in old age is often lethal. People age 85 and older have the highest suicide rate of all age groups (see the Social Issues: Health box on pages 618–619). What factors enable people like Ruth to surmount the physical impairment–depression relationship, remaining content? Personal characteristics discussed in this and earlier chapters—optimism, sense of self-efficacy, and effective coping—are vitally important (Morrison, 2008). But for frail aging adults to display these attributes, families and caregivers must avoid the dependency–support script and, instead, encourage their autonomy.

Unfortunately, older adults generally do not get the mental health care they need—even in nursing homes, where depression and other mental health problems are widespread (Hoeft et al., 2016; Karel, Gatz, & Smyer, 2012). More than half of U.S. nursing home residents receive no regular mental health intervention.

## Negative Life Changes

Ruth lost Walt to a heart attack, cared for her sister Ida as her Alzheimer’s symptoms worsened, and faced health problems of her own—all within a span of a few years. Older people are at

risk for a variety of negative life changes—death of loved ones, illness and physical disabilities, declining income, and greater dependency. Negative life changes are difficult for everyone but may actually evoke less stress and depression in older than in younger adults (Charles, 2011). Many older people have learned to cope with hard times, to appraise negative changes as common and expected in late life, and to accept loss as part of human existence.

Still, when negative changes pile up, they test the coping skills of older adults. In very old age, such changes are greater for women than for men. Women over age 75 are far less likely to be married, more often have lower incomes, and suffer from more illnesses—especially ones that restrict mobility. Furthermore, older women (as at younger ages) more often say that others depend on them for caregiving and emotional support. Consequently, their social relations, even in very old age, are more often a source of stress (Antonucci, Ajrouch, & Birditt, 2008). And because of their own declining health, older women may not be able to meet others’ needs for care—circumstances associated with chronic, high distress (Charles, 2010). Not surprisingly, women of advanced age tend to report lower psychological well-being than do men (Henning-Smith, 2016).

## Social Support

In late adulthood, social support continues to reduce stress, thereby promoting physical health and psychological well-being. Availability of social support increases the odds of living longer (Fry & Debats, 2006, 2010). And it helps explain the relationship of religious participation to survival, discussed earlier. Usually, older adults receive informal assistance with tasks of daily living from family members—first from their spouse or, if none exists, from children and then from siblings. If these individuals are not available, other relatives and friends may step in.

Nevertheless, many older people place such high value on independence that they do not want extensive help from others close to them unless they can reciprocate. In one investigation, providing intangible assistance (such as errands, transportation, or child care) to friends and relatives and emotional support to one’s spouse better predicted reduced mortality than receiving social support (Brown et al., 2003). When assistance is excessive or cannot be returned, it often interferes with self-efficacy and amplifies psychological stress (Warner et al., 2011). Perhaps for this reason, adult children express a deeper sense of obligation toward their aging parents than their parents expect from them (see Chapter 16, page 555). Formal support—a paid home helper or agency-provided services—as a complement to informal assistance not only helps relieve caregiving burden but also spares aging adults from feeling overly dependent in their close relationships.

Ethnic minority older adults, however, do not readily accept formal assistance. But they are more willing to do so when home helpers are connected to a familiar neighborhood organization, especially their religious community. Although African-American older people say they rely more on their families than on the

## Social Issues: Health

### Elder Suicide

When Abe's wife died, he withdrew from life, mostly spending his days alone. As grandchildren were born, Abe visited his daughters' families from time to time, carrying his despondent behavior with him. "Look at my new pajamas, Grandpa!" Abe's grandson Tony exclaimed on one occasion. Abe didn't respond.

When in his eighties, Abe developed painful digestive difficulties. His depression deepened, but he refused to see a doctor. "Don't need to," he said abruptly when one of his daughters begged him to get medical attention. Answering her invitation to Tony's tenth birthday party, Abe wrote, "Maybe—if I'm still around next month." Two weeks later, Abe died from an intestinal blockage. His body was found in the living room chair where he habitually spent his days. Although it may seem surprising, Abe's self-destructive acts are a form of suicide.

#### Factors Related to Elder Suicide

In most countries around the world, suicide increases over the lifespan, with older adults at greatest risk, though regional variations exist. As noted in Chapter 16, the United States is distinguished by a sharp rise in suicide in

middle adulthood (see page 546). Thereafter, the suicide rate levels off or drops slightly, increasing once again from age 75 on to a level that, at age 85 and older, slightly exceeds the midlife incidence (American Foundation for Suicide Prevention, 2016).

U.S. suicides among the very old have risen by 15 percent over the past few years—a trend (as in middle adulthood) largely accounted for by white men. Furthermore, the sex difference in suicide widens in old age: Nearly 10 times as many U.S. aging men as women take their own lives (Centers for Disease Control and Prevention, 2016d). Compared with the white majority, most ethnic minority older adults have low suicide rates.

What explains these differences? Despite the lifelong pattern of higher rates of depression among females, older women's closer ties to family and friends, willingness to seek social support, and greater religiosity prevent many from taking their own lives. High levels of social support through extended families and religious institutions may prevent suicide among ethnic minorities (Conwell, Van Orden, & Caine, 2011). And within certain groups, such as Alaskan Natives, deep respect for and reliance on older adults to teach

cultural traditions strengthen self-esteem and social integration. This reduces suicide, making it almost nonexistent after age 80 (Herne, Bartholomew, & Weahkee, 2014; Kettl, 1998).

Failed suicides are rare in old age. The ratio of attempts to completions for adolescents and young adults is as high as 200 to 1; for aging adults, it is 4 to 1 or lower (Conwell & O'Reilly, 2013). When older people decide to die, they are especially determined to succeed.

Underreporting of suicides probably occurs at all ages, but it is more common in old age. Many older adults, like Abe, engage in indirect self-destructive acts rarely classified as suicide—deciding not to go to a doctor when ill or refusing to eat or take prescribed medications. Among institutionalized older adults, these efforts to hasten death are widespread (Reiss & Tishler, 2008b). Consequently, suicide in late life is a larger problem than statistics indicate.

Two types of events prompt suicide in late life. Losses—retirement from a highly valued occupation, widowhood, or social isolation—place older adults who have difficulty coping with change at risk for persistent depression. Most suicides, however, stem from chronic and terminal illnesses that severely reduce physical functioning or cause intense pain

church for assistance, those with support and meaningful roles in both contexts fare best in mental health (Chatters et al., 2015). Compared to their white counterparts, African-American aging adults who attend church regularly are more involved in both giving and receiving diverse forms of social support—a difference largely explained by stronger social networks and shared values and goals among black congregants (Hayward & Krause, 2013a). But support from religious congregants has psychological benefits for older adults of all backgrounds, perhaps because the warm atmosphere of religious organizations fosters a sense of social acceptance.

Overall, for social support to foster well-being, older adults must take personal control of it. Help that is not wanted or needed or that exaggerates weaknesses results in poor person–environment fit, undermines mental health, and—if existing skills fall into disuse—accelerates physical disability. In contrast, help that increases autonomy—that frees up energy for endeavors that are

personally satisfying and that lead to growth—enhances quality of life. These findings clarify why *perceived social support* (older adults' sense of being able to count on family or friends in times of need) is associated with a positive outlook in older adults with disabilities, whereas sheer *amount* of help family and friends provide has little impact (Uchino, 2009).

Finally, besides various types of assistance, older adults benefit from social support that offers affection, affirmation of their self-worth, and sense of belonging. Extroverted older people are more likely to take advantage of opportunities to engage with others, thereby reducing loneliness and depression and fostering self-esteem and life satisfaction (Mroczek & Spiro, 2005). But as we will see in the next section, gratifying social ties in old age have little to do with quantity of contact. Instead, high-quality relationships, involving expressions of kindness, encouragement, respect, and emotional closeness, have the greatest impact on mental health in late life.

(Conwell et al., 2010). As comfort and quality of life diminish, feelings of hopelessness and helplessness deepen.

Mild cognitive declines, especially in executive function, make some individuals susceptible to impulsivity and poor problem solving, heightening suicidal risk when losses or illnesses arise (Dombrowski et al., 2008). Dementia is also linked to suicide, especially shortly after diagnosis (Haw, Harwood, & Hawton, 2009).

The chances of suicide are further elevated when a sick older person is socially isolated—living alone or in a nursing home with high staff turnover, minimal caregiver support, and little opportunity for personal control over daily life. Suicide rates are lower in European countries where older people more often live with their families (Yur'yev et al., 2010). At the same time, when ill aging adults perceive themselves to be a burden to their families, the risk of suicide rises (Yip et al., 2010).

### Prevention and Treatment

Warning signs of suicide in late adulthood, like those at earlier ages, include statements about dying, despondency, and sleep and appetite changes. But family members, friends, caregivers, and health professionals must also watch for indirect self-destructive acts that are unique to old age, such as refusing food or medical treatment.

When suicidal aging adults are depressed, the most effective treatment combines antidepressant medication with therapy, including help in coping with role transitions, such as retirement, widowhood, and dependency brought about by illness. Distorted ways of thinking (“I’m old—nothing can be done about my problems,” “I’m burdening my children”) must be countered and revised. Meeting with the family to find ways to reduce loneliness and desperation is also helpful.

Communities are beginning to recognize the importance of preventive steps, such as community-wide screenings for risk factors, programs that help aging adults cope with life transitions, telephone hot lines with trained volunteers who provide emotional support, and agencies that arrange for regular home visitors or “buddy system” phone calls (Draper, 2014). But so far, most of these efforts benefit women more than men because women are more likely to tell health professionals about high-risk symptoms, such as despondency, and to use social resources.

Finally, suicide in late life raises a controversial ethical issue: Do people with incurable illnesses have the right to take their own lives? We will take up this topic in Chapter 19.

GOLDEN PIXELS LLC/ALAMY

U.S. suicide rates among the very old have recently increased, especially among white men. Most late-life suicides arise from illnesses that severely interfere with comfort and quality of life. Social isolation further increases suicide risk.

## Ask yourself

**CONNECT** Why is it important to understand aging adults' *perceptions* of their circumstances—physical changes (see page 579 in Chapter 17), health, negative life changes, and social support? How do the perceptions of most older people promote psychological well-being?

**APPLY** At age 85, Miriam took a long time to get dressed. Joan, her home helper, said, “From now on, don’t get dressed until I get there. Then I can help, and it won’t take so long.” What impact is Joan’s approach likely to have on Miriam’s personality? What alternative approach would you recommend?

**REFLECT** Among older people you know, do any fit the description of a Third Ager? Explain.

## A Changing Social World

**18.5** Describe the limitations of disengagement theory and activity theory, and explain the more recent perspectives of continuity theory and socioemotional selectivity theory.

**18.6** How do communities, neighborhoods, and housing arrangements affect older adults' social lives and adjustment?

Walt and Ruth’s outgoing personalities led many family members and friends to seek them out, and they often reciprocated. In contrast, Dick’s stubborn nature meant that he and Goldie, for many years, had had a far more restricted network of social ties.

As noted earlier, extroverts (like Walt and Ruth) continue to interact with a wider range of people than do introverts and people (like Dick) with poor social skills. Nevertheless, both

cross-sectional and longitudinal research confirms that size of social networks and, therefore, amount of social interaction decline for virtually everyone (Antonucci, Akiyama, & Takahashi, 2004; Charles & Carstensen, 2009). This finding presents a curious paradox: If social interaction and social support are essential for mental health, how is it possible for older adults to interact less yet be generally satisfied with life and less depressed than younger adults?

## Social Theories of Aging

Social theories of aging offer explanations for changes in aging adults' social activity. Two older perspectives interpret declines in social interaction in opposite ways.

According to *disengagement theory*, older people decrease their activity levels and interact less frequently, becoming more preoccupied with their inner lives in anticipation of death (Cumming & Henry, 1961). Yet clearly, most older adults don't disengage! Many sustain aspects of their work, with some moving into new positions of prestige and power (see Chapter 17). And others develop new, rewarding roles in their communities.

Attempting to overcome the flaws of disengagement theory, *activity theory* proposes that social barriers to engagement, not the desires of older adults, cause declining rates of interaction. Older people who lose certain roles and relationships (for example, through retirement or widowhood) try to find others in an effort to stay active—conditions that promote life satisfaction (Maddox, 1963). However, when health status is controlled, older people who have larger social networks and engage in more activities are not necessarily happier (Charles & Carstensen, 2009). Recall that quality, not quantity, of relationships predicts psychological well-being in old age.

More recent approaches—continuity theory and socioemotional selectivity theory—view older adults' social engagement as influenced by both late-life psychological changes and social contexts. Consequently, they account for a wider range of findings.

**Continuity Theory.** According to **continuity theory**, most aging adults strive to maintain a personal system—an identity and a set of personality dispositions, interests, roles, and skills—that promotes life satisfaction by ensuring consistency between their past and anticipated future. This striving for continuity does not mean that older people's lives are static. To the contrary, aging produces inevitable change, but older adults try to minimize stress and disruptiveness by integrating those changes into a coherent, consistent life path, drawing on well-practiced strategies acquired over a lifetime. As much as possible, they choose to use familiar skills and engage in familiar activities with familiar people—preferences that provide a secure sense of routine and direction in life.

Research confirms a high degree of continuity in older adults' everyday pursuits and relationships. For most, friends and family members with whom they interact remain much the same, as do work, volunteer, leisure, and social activities. Even after a change (such as retirement), people usually make choices that

WARING ABBOTT/GETTY IMAGES

These career musicians perform after retirement as members of a community band—continuity that affirms their identity, sustains rewarding relationships and interests, and promotes self-esteem and life satisfaction.

extend the previous direction of their lives, engaging in new activities but often within familiar domains. For example, a retired manager of a children's bookstore collaborated with friends to build a children's library and donate it to an overseas orphanage. A musician who, because of arthritis, could no longer play the violin arranged regular get-togethers with musically inclined friends to listen to and talk about music. Robert Atchley (1989), originator of continuity theory, noted, "Everyday life for most older people is like long-running improvisational theater in which ... changes are mostly in the form of new episodes [rather] than entirely new plays" (p. 185).

Aging adults' reliance on continuity has many benefits. Participating in familiar activities with familiar people provides repeated practice that helps preserve physical and cognitive functioning, fosters self-esteem and mastery, and affirms identity (Finchum & Weber, 2000; Vacha-Haase, Hill, & Birmingham, 2012). Investing in long-standing, close relationships provides comfort, pleasure, and a network of social support. Finally, striving for continuity is essential for attaining Erikson's sense of ego integrity, which depends on preserving a sense of personal history (Atchley, 1999).

As we explore social contexts and relationships of aging, we will encounter many examples of how older adults use continuity to experience aging positively, as a "gentle slope." We will also address ways that communities can help them do so. As our discussion will reveal, people experiencing the greatest disruption to desired continuity in activities and lifestyle preferences have the most difficulty adapting to growing older.

**Socioemotional Selectivity Theory.** How do people's social networks sustain continuity while also narrowing as they age? According to **socioemotional selectivity theory**, social interaction in late life extends lifelong selection processes. In middle adulthood, marital relationships deepen, siblings feel closer, and number of friendships declines. As people age, contacts with family and friends are sustained until the eighties, when they diminish gradually in favor of a few very close relationships. In contrast, as Figure 18.1 shows, relationships with

**FIGURE 18.1** Age-related changes in number of social partners varying in closeness. Nearly 200 adults ranging in age from early to late adulthood were followed for a decade, during which they were periodically asked to list people in their social networks whom they felt “very close to,” “not quite so close to,” and “less close to.” Total social network size decreased sharply from middle to late adulthood. The drop was largely accounted for by “not quite so close” and “less close” social partners. “Very close” partners declined minimally. (From T. English & L. L. Carstensen, 2014, “Selective Narrowing of Social Networks Across Adulthood Is Associated with Improved Emotional Experience in Daily Life,” *International Journal of Behavioral Development*, 38, p. 199. Adapted by permission of Sage Publications.)

people to whom one feels less close decline steeply from middle through late adulthood (Carstensen, 2006; English & Carstensen, 2014; Wrzus et al., 2013).

What explains these changes? Socioemotional selectivity theory states that aging leads to changes in the functions of social interaction. Consider the reasons you interact with members of your social network. At times, you approach them to get information. At other times, you seek affirmation of your worth as a person. You also choose social partners to regulate emotion, approaching those who evoke positive feelings and avoiding those who make you feel sad, angry, or uncomfortable. For older adults, who have gathered a lifetime of information, the information-gathering function becomes less significant. Also, they realize it is risky to approach people they do not know for self-affirmation: Negative stereotypes of aging increase the odds of receiving a condescending, hostile, or indifferent response.

Instead, older adults emphasize the emotion-regulating function of interaction. In one study, younger and older adults were asked to categorize their social partners. Younger people more often sorted them on the basis of information seeking and future contact, whereas older people emphasized anticipated feel-

ings (Frederickson & Carstensen, 1990). They appeared highly motivated to approach pleasant relationships and avoid unpleasant ones. Notice how, by interacting mostly with close relatives and friends, older people engage in a form of anticipatory emotion regulation: They increase the chances that their emotional equilibrium will be preserved.

Within close bonds, aging adults actively apply their emotional expertise to promote harmony. Recall from our discussion of the positivity effect that older adults are more likely than younger people to resolve interpersonal conflicts constructively (see page 611). They also reinterpret conflict in less stressful ways—often by identifying something positive in the situation (Labouvie-Vief, 2003). Consequently, despite their smaller social networks, they are happier than younger people with their number of friends and report fewer problematic relationships and less distress when they encounter interpersonal tensions (Blanchard-Fields & Coats, 2008; Fingerman & Birditt, 2003).

Extensive research confirms that people’s perception of time is strongly linked to their social goals. If you faced a shortened future, with whom would you choose to spend time? When remaining time is limited, adults *of all ages* place more emphasis on the emotional quality of their social experiences. They shift from focusing on long-term goals to emphasizing emotionally fulfilling relationships in the here and now (Charles & Carstensen, 2010). Similarly, aging adults—aware that time is “running out”—don’t waste it on unlikely future payoffs but, instead, turn to close friends and family members. Furthermore, we generally take special steps to facilitate positive interaction with people dear to us whose time is limited—for example, treating older friends and relatives more kindly than younger ones, easily excusing or forgiving their social transgressions (Luong,

© DAVID M. GROSSMAN/THE IMAGE WORKS

These sisters—ages 93 and 89—greet each other with enthusiasm. The one on the right traveled from Poland to New York City for this reunion. To preserve emotional equilibrium and reduce stress, older adults increasingly emphasize familiar, emotionally rewarding relationships.

Charles, & Fingerma, 2011). In this way, social partners contribute to older adults' gratifying relationship experiences.

Aging adults' emphasis on *relationship quality* helps explain a cultural exception to the restriction of social relationships just described. In collectivist societies, where people value an interdependent self and attach great importance to remaining embedded in their social group, older people may be motivated to sustain high-quality ties with all partners! In line with this prediction, in a Hong Kong study, aging adults scoring high in interdependence both expanded their number of emotionally close social partners and preserved the same number of peripheral social partners into advanced old age (Yeung, Fung, & Lang, 2008). In contrast, Hong Kong older people scoring low in interdependence resembled their Western counterparts: They gradually limited their social ties to a few close relationships.

In sum, socioemotional selectivity theory views older adults' preference for high-quality, emotionally fulfilling relationships as largely due to their contracting future and the preciousness of time. But the meaning of relationship quality and, therefore, the number and variety of people to whom older people turn for pleasurable interaction and self-affirmation vary with culture.

## Social Contexts of Aging: Communities, Neighborhoods, and Housing

The physical and social contexts in which aging adults live affect their social experiences and, consequently, their development and adjustment. Communities, neighborhoods, and housing arrangements vary in the extent to which they enable older residents to satisfy their social needs.

**Communities and Neighborhoods.** About half of U.S. ethnic minority older adults live in cities, compared with just one-third of European Americans. The majority of older people reside in suburbs, where they moved earlier in their lives and usually remain after retirement. Suburban older adults have higher incomes and report better health than their inner-city counterparts do. But inner-city older people are better off in terms of public transportation. As declines in physical functioning compromise out-of-home mobility, convenient bus, tram, and rail lines become increasingly important to life satisfaction and psychological well-being (Eibich et al., 2016; Mollenkopf, Hieber, & Wahl, 2011). Furthermore, city-dwelling aging adults fare better in terms of health, income, and proximity of cultural activities and social services than do the one-fifth of U.S. older people who live in small towns and rural areas (U.S. Department of Health and Human Services, 2015e). In addition, small-town and rural aging adults are less likely to live near their children, who often leave these communities in early adulthood.

Yet small-town and rural older people compensate for distance from children and social services by establishing closer relationships with nearby extended family and by interacting more with neighbors and friends (Hooyma, Kawamoto, & Kiyak, 2015; Shaw, 2005). Smaller communities have features that foster gratifying relationships—stability of residents, shared

MARGIE POLITZER/GETTY IMAGES

When aging adults live in a neighborhood with many like-minded older residents, spontaneous gatherings like this one, involving stimulating, pleasurable conversation, happen more often.

values and lifestyles, willingness to exchange social support, and frequent social visits as country people “drop in” on one another. And many suburban and rural communities have responded to aging residents' needs by developing transportation programs (such as special buses and vans) to take them to health and social services, senior centers, and shopping centers.

Both urban and rural older people report greater life satisfaction when many aging adults reside in their neighborhood and are available as like-minded companions. Presence of family is less crucial when neighbors and nearby friends provide social support (Gabriel & Bowling, 2004). This does not mean that neighbors replace family relationships. But older adults are content as long as their children and other relatives who live far away arrange occasional visits and otherwise stay in touch through phone calls and social media (Hooyma, Kawamoto, & Kiyak, 2015).

Compared with those in urban areas, aging adults in quiet neighborhoods in small and midsized communities tend to be more satisfied with life. In addition to a friendlier, more supportive atmosphere, smaller communities have lower crime rates (Eibich et al., 2016; Krause, 2004). As we will see next, fear of crime has profound, negative consequences for older people's sense of security and comfort.

**Victimization and Fear of Crime.** Walt and Ruth's single-family home stood in an urban neighborhood, five blocks from the business district where Walt's photography shop had been prior to his retirement. As the neighborhood aged, some homes fell into disrepair, and the population became more transient. Although they had never been victimized, crime was on Walt and Ruth's minds and affected their behavior: They avoided neighborhood streets after sundown.

Media attention has led to a widely held belief that crime against older adults is common. In reality, they are less often targets of crime, especially violent crime, than other age groups. In urban areas, however, purse snatching and pickpocketing are more often committed against aging adults (especially women)

than younger people (U.S. Department of Justice, 2015). A single incident can strike intense anxiety into the hearts of older people because of its potential for physical injury and its financial consequences for those with low incomes.

Among frail aging adults living alone and in inner-city areas, fear of crime, which is sometimes greater than worries about income, health, and housing, restricts activities and undermines morale (Beaulieu, Leclerc, & Dube, 2003). In one study, older adults who had experienced a violent crime were more likely than those with physical and cognitive impairments to enter a nursing home (Lachs et al., 2006). Neighborhood Watch and other programs that encourage residents to look out for one another increase communication among neighbors, strengthen sense of neighborhood cohesion, and reduce fear (Oh & Kim, 2009).

**Housing Arrangements.** Older people's housing preferences reflect a strong desire for **aging in place**—remaining in a familiar setting where they have control over their everyday life. Overwhelmingly, aging adults in Western nations want to stay in the neighborhoods where they spent their adult lives; in fact, 90 percent remain in or near their old home. In the United States, only about 4 percent relocate to other communities (U.S. Department of Health and Human Services, 2015e). These moves are usually motivated by a desire to live closer to children or, among the more economically advantaged and healthy, a desire for a more temperate climate and a place to pursue leisure interests.

Most relocations occur within the same town or city and are prompted by declining health, widowhood, or disability (Bekhet, 2016). As we look at housing arrangements for older adults, we will see that the more a setting deviates from home life, the harder it is for older people to adjust.

**Ordinary Homes.** For the majority of aging adults, who are not physically impaired, staying in their own homes affords the greatest possible personal control—freedom to arrange space and schedule daily events as one chooses. More older people in Western countries live on their own today than ever before—a trend due to improved health and economic well-being (U.S. Department of Health and Human Services, 2015e). But when health and mobility problems appear, independent living poses risks to an effective person–environment fit. Most homes are designed for younger people. They are seldom modified to suit the physical capacities of their older residents.

When Ruth reached her mid-eighties, Sybil begged her to move into her home. Like many adult children of Southern, Central, and Eastern European descent (Greek, Italian, Polish, and others), Sybil felt an especially strong obligation to care for her frail mother. Older adults of these cultural backgrounds, as well as African Americans, Asians, Hispanics, and Native Americans, more often live in extended families (see page 555 in Chapter 16).

Yet increasing numbers of ethnic minority older people want to live on their own, although poverty often prevents them from doing so. For example, two decades ago, most Asian-American aging adults were living with their children, whereas today 65 percent live independently—a trend also evident in certain

Asian nations, such as Japan (Federal Interagency Forum on Aging Related Statistics, 2012; Takagi & Silverstein, 2011). With sufficient income to keep her home, Ruth refused to move in with Sybil. Continuity theory helps us understand why many older adults react this way, even after health problems accumulate. As the site of memorable life events, the home strengthens continuity with the past, preserving a sense of identity in the face of physical declines and social losses. And it permits older adults to adapt to their surroundings in familiar, comfortable ways. Older people also value their independence, privacy, and network of nearby friends and neighbors.

Over the past half century, the number of unmarried, divorced, and widowed aging adults living alone has increased dramatically. Nearly 30 percent of U.S. older adults live by themselves, a figure that rises to nearly 50 percent for those age 85 and older (U.S. Department of Health and Human Services, 2015e). This trend, though evident in all segments of the aging population, is less pronounced among men, who are far more likely than women to be living with a spouse into advanced old age.

Over 35 percent of U.S. older adults who live alone are poverty-stricken—a rate far greater than among older couples. More than 70 percent are widowed women. Because of lower earnings in earlier years, some entered old age this way. Others became poor for the first time, often because they outlived a spouse who suffered a lengthy, costly illness. With age, their financial status worsens as their assets shrink and their own health-care costs rise (National Institute on Retirement Security, 2016). Under these conditions, isolation, loneliness, and depression can pile up. Poverty among lone aging women is deeper in the United States than in other Western nations because of less generous government-sponsored income and health benefits. Consequently, the feminization of poverty deepens in old age.

**Residential Communities.** About 12 percent of U.S. adults age 65 and older live in residential communities, a proportion that rises with age as functional limitations increase. Among people age 85 and older, 27 percent live in these communities, which come in great variety (Freedman & Spillman, 2014). Housing developments for aging adults, either single-dwelling or apartment complexes, differ from ordinary homes only in that they have been modified to suit older adults' capacities (featuring, for example, single-level living space and grab bars in bathrooms). Some are federally subsidized units for low-income residents, but most are privately developed retirement villages with adjoining recreational facilities.

For older adults who need more help with everyday tasks, *assisted-living* arrangements are available (see Chapter 17, page 593). **Independent living communities**—an increasingly popular option—provide a variety of hotel-like support services, including meals in a common dining room, housekeeping, laundry services, transportation assistance, and recreational activities. **Life-care communities** offer a continuum of housing alternatives: independent living, residences providing personal and health-related services to accommodate older adults with physical and mental disabilities, and full nursing home care. For a large initial payment and additional monthly fees, life care

MARK LYONS/THE NEW YORK TIMES/REXUS

Residents of a life-care community gather for a meal in the common dining room. By providing a range of housing alternatives plus personal and health-related services and care, life-care communities meet older adults' changing needs within the same facility as they age.

guarantees that individuals' changing needs will be met within the same facility as they age.

Unlike Ruth and Walt, who remained in their own home, Dick and Goldie decided in their late sixties to move to a nearby life-care community. For Dick, the move was a positive turn of events that permitted him to relate to peers on the basis of their current life together, setting aside past failures in the outside world. Dick found gratifying leisure pursuits—leading an exercise class, organizing a charity drive with Goldie, and using his skills as a baker to make cakes for birthday and anniversary celebrations.

By sustaining an effective person–environment fit as older adults' capacities change, life-care communities have positive effects on physical and mental health. A specially designed physical space plus personal and health-related assistance on an as-needed basis help older people cope with mobility and self-care limitations, enabling greater social participation and a more active lifestyle (Croucher, Hicks, & Jackson, 2006; Jenkins, Pienta, & Horgas, 2002). And in societies where old age leads to reduced status, age-segregated living is gratifying to most who choose it. It may open up useful roles and leadership opportunities. The more older adults perceive the environment as socially supportive, the more they collaborate with one another in coping with stressors of aging and in providing assistance to other residents (Lawrence & Schigelone, 2002). Residential communities appear to be well-suited to promoting mutually supportive relationships.

Nevertheless, no U.S. federal regulations govern assisted-living facilities, which vary widely in quality. Low-income ethnic minority aging adults are less likely to use assisted living. When older people with limited financial resources do transition to assisted living, they usually lack control over when and where they move and enter lower-quality settings—conditions associated with high stress. Nearly 42 percent of residents in assisted-living facilities report having experienced an unmet need during the past month, mostly related to self-care but also to getting

around inside and getting outside (Ball et al., 2009; Freedman & Spillman, 2014). And in some states, assisted-living facilities are prohibited from providing any nursing care and medical monitoring, requiring residents to leave when their health declines (National Center for Assisted Living, 2013).

Yet physical designs and support services that enable aging in place are vital for older adults' well-being. These include homelike surroundings, division of large environments into smaller units to facilitate meaningful activities, social roles and relationships, and the latest assistive technologies to permit adaptation to changing health needs (Oswald & Wahl, 2013).

Shared values and goals among residents with similar backgrounds also enhance life satisfaction. Older adults who feel socially integrated into the setting are more likely to consider it their home. But those who lack like-minded companions are unlikely to characterize it as home and are at high risk for loneliness and depression (Adams, Sanders, & Auth, 2004; Cutchin, 2013).

**Nursing Homes.** About 3 percent of Americans age 65 and older live in nursing homes, nearly half of whom are 85 and older (Bern-Klug & Manthai, 2016). They experience the most extreme restriction of autonomy and social integration. Although potential companions are abundant, interaction is low. To regulate emotion in social interaction (so important to aging adults), personal control over social experiences is vital. Yet nursing home residents have little opportunity to choose their social partners, and timing of contact is generally determined by staff rather than by residents' preferences. Social withdrawal is an adaptive response to these often overcrowded, hospital-like settings, which typically provide few ways for residents to use their competencies. Although interaction with people in the outside world predicts nursing home residents' life satisfaction, interaction within the institution does not (Baltes, Wahl, & Reichert, 1992). Not surprisingly, nursing home residents with physical but not mental impairments are far more depressed, anxious, and lonely than their community-dwelling counterparts (Guildner et al., 2001).

Designing more homelike nursing homes could help increase residents' sense of security and control. U.S. nursing homes, usually operated for profit, are often packed with residents and institutional in their operation. In contrast, European facilities are liberally supported by public funds and resemble high-quality assisted living.

In a radically changed U.S. nursing home concept called THE GREEN HOUSE<sup>®</sup> model, a large, outdated nursing home in Mississippi was replaced by 10 small, self-contained houses (Rabig et al., 2006). Each is limited to 10 or fewer residents, who live in private bedroom–bathroom suites that surround a family-style communal space. Besides providing personal care, a stable staff of nursing assistants fosters aging adults' control and independence. Residents determine their own daily schedules and are invited to join in both recreational and household activities, including planning and preparing meals, cleaning, gardening, and caring for pets. A professional support team—including

© 2009 LYNN JOHNSON

THE GREEN HOUSE® model blurs distinctions among nursing home, assisted living, and “independent” living. In this homelike setting, residents determine their own daily schedules and help with household tasks. Green House living environments now exist in more than 30 U.S. states.

licensed nurses, therapists, social workers, physicians, and pharmacists—visits regularly to serve residents’ health needs. In comparisons of Green House residents with traditional nursing home residents, Green House older adults reported substantially better quality of life, and they also showed less decline over time in ability to carry out activities of daily living (Kane et al., 2007).

The Green House model—and other models like it—is blurring distinctions among nursing home, assisted living, and “independent” living. By making the home a central, organizing principle, the Green House approach includes all the aging-in-place and effective person–environment fit features that ensure late-life well-being: physical and emotional comfort, enjoyable daily pursuits enabling residents to maximize use of their capacities, and meaningful social relationships.

## Ask yourself

**CONNECT** According to socioemotional selectivity theory, when time is limited, adults focus on the emotional quality of their social relationships. How do older people apply their emotional expertise (discussed on page 621) to attain this goal?

**APPLY** Sam lives alone in the same home he has occupied for over 30 years. His adult children cannot understand why he won’t move across town to a modern apartment. Using continuity theory, explain why Sam prefers to stay where he is.

**REFLECT** Imagine yourself as a resident in an assisted-living facility. List all the features you would want your living context to have, explaining how each helps ensure effective person–environment fit and favorable psychological well-being.

## Relationships in Late Adulthood

- 18.7** Describe changes in relationships in late adulthood, including marriage, lesbian and gay partnerships, divorce, remarriage, and widowhood, and discuss never-married, childless older adults.
- 18.8** How do sibling relationships and friendships change in late life?
- 18.9** Describe older adults’ relationships with adult children and adult grandchildren.
- 18.10** Discuss elder maltreatment, including risk factors, consequences, and prevention strategies.

The **social convoy** is an influential model of changes in our social networks as we move through life. Picture yourself in the midst of a cluster of ships traveling together, granting one another safety and support. Ships in the inner circle represent people closest to you, such as a spouse, best friend, parent, or child. Those less close, but still important, travel on the outside. With age, ships exchange places in the convoy, and some drift off while others join the procession (Antonucci, Birditt, & Ajrouch, 2011; Antonucci, Birditt, & Akiyama, 2009). As long as the convoy continues to exist, you adapt positively.

In the following sections, we examine the ways older adults with diverse lifestyles sustain social networks of family members and friends. As ties are lost, older adults draw others closer, and most cultivate new network members, though not at the rate they did at younger ages (Cornwell & Laumann, 2015). Although size of the convoy decreases as agemates die, aging adults are rarely left without people in their inner circle who contribute to their well-being—a testament to their resilience in maintaining effective social networks (Fiori, Smith, & Antonucci, 2007). But for some, tragically, the social convoy breaks down. We will also explore the circumstances in which older people experience abuse and neglect at the hands of those close to them.

## Marriage

It has long been believed, on the basis of cross-sectional research, that marital satisfaction rises from middle to late adulthood. Longitudinal evidence, however, reveals that this seeming upturn in marital happiness is due to a cohort effect (Proulx, 2016; VanLaningham, Johnson, & Amato, 2001). Walt’s comment to Ruth that “the last few decades have been the happiest” may have resulted in part from the time period in which they married—the 1950s. By the 1980s, an array of societal changes presented substantial challenges to marital contentment: a rise in U.S. families experiencing financial hardship, increased role overload as more married women moved into the work force, greater disagreement over gender-role expectations related to marital roles, and more individualistic attitudes toward marriage (see Chapters 14 and 16).

As in early and middle adulthood, paths of late-life marital satisfaction are diverse (Proulx, 2016). In one study, 700 people who remained continuously married were first interviewed in 1980 and then reinterviewed periodically over the next two

decades, enabling researchers to track satisfaction in marriages that had endured for as long as 40 to 50 years. As Figure 18.2 reveals, participants fell into five patterns: two high and stable, one lower and stable, one declining followed by a rise in late life, and one declining steadily from early into late adulthood (Anderson, Van Ryzin, & Doherty, 2010). Reported marital problems and time spent in shared activities tended to parallel these paths. In addition, the steadily declining pattern had the highest percentage of individuals with financial difficulties.

Notice in Figure 18.2 that two-thirds of the participants maintained stable, happy marriages throughout adulthood. Also, lower marital quality reversed in late adulthood only for individuals who early on had experienced a rewarding marriage. Perhaps the memory of former happier times created a goal for older couples to strive for once stressful responsibilities, such as rearing children and balancing the demands of career and family, had diminished.

How do the majority of aging adults maintain highly satisfying marriages? Greater emphasis on regulating emotion in relationships may lead to more positive interactions between spouses. Aging couples, compared to younger couples, resolve their differences in more constructive ways (Hatch & Bulcroft, 2004). Even in poor-quality marriages, older adults attempt to prevent disagreements from escalating into expressions of anger and resentment (Hatch & Bulcroft, 2004). For example, when Dick complained about Goldie's cooking, Goldie tried to appease him: "All right, Dick, next birthday I won't make cheesecake." And when Goldie brought up Dick's bickering and criticism, Dick usually said, "I

know, dear," and retreated to another room. As in other relationships, older people try to protect themselves from stress by molding marital ties to make them as pleasant as possible.

Aging married couples do admit to times their partner gets on their nerves or makes too many demands—more so than they say their adult children or best friends do (Birditt, Jackey, & Antonucci, 2009). But these expressions are usually mild, and they likely result from frequent contact, yielding greater opportunity for minor annoyances.

Finally, compared to their single agemates, married older people generally have larger social networks of both family members and friends, with whom they interact more frequently. As long as aging adults report mostly high-quality ties, this relationship profile provides for social engagement and support from a variety of sources and is linked to higher psychological well-being (Birditt & Antonucci, 2007). These benefits, combined with a long history of caring concern from an intimate partner, may explain the strengthening association of marriage with good health in late adulthood (Holt-Lunstad, Smith, & Layton, 2010; Yorgason & Stott, 2016). Late-life marriage is linked to lower rates of chronic illness and disability and increased longevity.

When marital dissatisfaction exists, however, even having close, high-quality friendships cannot reduce its profoundly negative impact on well-being. A poor marriage often takes a greater toll on women than on men (Birditt & Antonucci, 2007; Boerner et al., 2014). Recall from Chapter 14 that women more often try to work on a troubling relationship, yet in late life, expending energy in this way is especially taxing, both physically and mentally. Men, in contrast, are more likely to protect themselves by withdrawing and avoiding discussion.

## Lesbian and Gay Couples

Older lesbians and gay men in long-term partnerships have sustained their relationships through a historical period of hostility and discrimination, finally gaining the right to marry in the United States in 2015. Nevertheless, most report happy, highly fulfilling relationships, pointing to their partner as their most important source of social support. Like their heterosexual counterparts, sexual minority older couples rate their physical and mental health more favorably than do their single lesbian and gay agemates (Williams & Fredriksen-Goldsen, 2014).

A lifetime of effective coping with an oppressive social environment may have strengthened lesbian and gay couples' skills at managing late-life physical and cognitive changes, thereby contributing to relationship satisfaction (Gabbay & Wahler, 2002). And changing social conditions, including the ease with which younger generations are embracing their sexual minority identities and "coming out," may have encouraged more older adults to do the same. Compared with same-sex couples not in a legally recognized relationship, those who are married are advantaged in physical and psychological well-being (Wight, LeBlanc, & Lee Badget, 2013). Their more favorable mental health is equivalent to that of older couples in long-term heterosexual marriages.

Because of strain in family relationships when they told others about their sexual orientation, lesbian and gay older adults

**FIGURE 18.2 Paths of marital happiness.** In a study of 700 continuously married people followed over two decades, participants displayed five patterns. Two thirds maintained high and stable marital satisfaction, whereas less than one-fifth displayed lower and stable satisfaction. A small minority showed a low, steadily declining pattern. Marital quality improved in late adulthood only for those who had experienced a happy marriage early on. (From J. R. Anderson, M. J. Van Ryzin, & W. J. Doherty, 2010, "Developmental Trajectories of Marital Happiness in Continuously Married Individuals: A Group-Based Modeling Approach," *Developmental Psychology*, 5, p. 591. Copyright ©2010 by the American Psychological Association. Adapted by permission.)

ROSARENEBETANCOURT ZIALAMY

The majority of aging adults in marriages and long-term partnerships, including same-sex couples, maintain highly satisfying relationships, which are associated with good health and increased longevity.

less often assumed during the course of their lives that family members would provide support in old age. Consequently, many have forged strong friendships to replace or supplement family ties (Richard & Brown, 2006). Sexual minority couples with gratifying friendship networks report high life satisfaction and reduced fear of aging (Slusher, Mayer, & Dunkle, 1996).

Nevertheless, because of continuing prejudice, aging lesbians and gay men face unique challenges. Health-care systems are often unresponsive to their unique needs. And those caring for a partner in poor health may be less likely to seek help from community agencies offering formal support services because of real or perceived discrimination (Zdaniuk & Smith, 2016). These circumstances can make late-life declines and losses especially stressful.

## Divorce, Remarriage, and Cohabitation

When Walt's uncle Louie was 65, he divorced his wife Sandra after 32 years of marriage. Although she knew the marriage was far from perfect, Sandra had lived with Louie long enough that the divorce came as a shock. A year later, Louie married Rachella, a divorcée who shared his enthusiasm for sports and dance.

Couples who divorce in late adulthood constitute less than 5 percent of all U.S. divorces in any given year. But divorce among people age 65 and older has quadrupled over the past three decades, currently affecting 13 percent of women and 11 percent of men (Mather, Jacobsen, & Pollard, 2015). New generations of older adults—especially the baby boomers—have become more accepting of late-life marital breakup as a means of attaining self-fulfillment and as the divorce risk increased for second and subsequent marriages.

Although one-fifth of older adults' dissolving marriages are of less than 10 years duration, about half are lengthy—30 years or more (Brown & Lin, 2012). Compared with younger adults, longtime married older people

have given their adult lives to the relationship. Following divorce, they find it harder to separate their identity from that of their former spouse and, therefore, may experience a greater sense of personal failure. Relationships with family and friends shift at a time when close bonds are crucial for psychological well-being.

As in middle adulthood, aging women are more likely than men to initiate divorce. This is despite the fact that the financial consequences for women generally are severe—greater than for widowhood because many accumulated assets are lost in property settlements (Sharma, 2015). Still, older people of both genders seldom express regret over leaving an unhappy marriage (Bair, 2007). Usually, they experience a sense of relief.

An estimated 14 percent of U.S. older adults, more men than women, are in a dating relationship, though dating declines with age (Brown & Shinohara, 2013). Aging baby boomers—accustomed to using the Internet for many purposes—are turning to online dating services and personal ads to search for new partners, though they use dating sites far less often than younger people do (Pew Research Center, 2013b). Older adults' personal ads indicate that they are more selective with respect to the age, race, religion, and income of a potential dating partner (McIntosh et al., 2011). And as Figure 18.3 shows, they more often refer to their own health issues and loneliness and less often to romance, sex, desire for a soulmate, and adventure than middle-aged people do (Alterovitz & Mendelsohn, 2013). In their search for the right person, they seem to take a candid, no-nonsense approach!

Remarriage rates are low in late adulthood, though widowed older adults remarry at a higher rate than divorcees (Brown, Bulanda, & Lee, 2012). Men more often succeed in finding a partner than women, as their opportunities to do so are far greater. Nevertheless, increasing age makes remarriage less

**FIGURE 18.3** Themes in online personal ads of middle-aged and older adults seeking dating partners. An analysis of themes in 450 ads revealed that older adults more often mention health issues and loneliness, whereas middle-aged adults place greater emphasis on romance, sex, finding a soulmate, and adventure. Older adults appear to be practical and direct in their search for a partner. (From S. S. R. Alterovitz and G. A. Mendelsohn, 2013, "Relationship Goals of Middle-Aged, Young-Old, and Old-Old Internet Daters: An Analysis of Online Personal Ads," *Journal of Aging Studies*, 27, p. 163. Copyright © 2013, Elsevier. Reprinted by permission of Elsevier, Inc.)

likely for both men and women, who frequently say they don't want to marry again (Mahay & Lewin, 2007). Common reasons include poorer health, a shortened future (making it hard to justify radical life change), concerns about adult children's acceptance of the new partner, desire to protect assets they have accumulated over their lifetime, and (especially for women) apprehension over the caregiving burden marriage might bring (Wu & Schimmele, 2007). Divorced men who remain single, however, no longer benefit from their former wives' kinkeeping role, are more likely to experience reduced contact and support from adult children, and more often move away from friends and neighbors (Daatland, 2007). For these reasons, they are at greater risk for adjustment difficulties.

Compared with younger people who remarry, older adults who do so enter more stable relationships, as their divorce rate is much lower. In Louie and Rachella's case, the second marriage lasted for 28 years! Perhaps late-life remarriages are more successful because they involve more maturity, patience, and a better balance of romantic with practical concerns. Good health and financial stability also contribute: Healthy, economically advantaged older people are more likely to repartner than those in declining health or experiencing financial strains (Brown, Bulanda, & Lee, 2012; Vespa, 2012). Remarried older couples are generally very satisfied with their new relationships, although men tend to be more content than women (Connidis, 2010). With fewer potential mates, perhaps women who remarry in late life settle for less desirable partners.

Rather than remarrying, older people who enter a new relationship are increasingly choosing cohabitation, a trend expected to continue as more baby boomers—the first generation to cohabit at high rates in early adulthood—reach late life. Like remarriage, cohabitation results in more stable relationships and higher relationship quality than it did at younger ages. And cohabiting aging adults are as satisfied with their partnered lives as are their married counterparts (Brown, Bulanda, & Lee, 2012; Brown & Kawamura, 2010). This suggests that cohabitation in late adulthood typically serves as a long-term alternative to marriage.

Finally, a growing number of repartnered older couples form relationships described as *living apart together*—an intimate, committed tie involving living separately, in their own homes. When asked why they choose this arrangement, aging adults mention the desire to maintain their independence, financially and otherwise, including—especially among women—avoiding having again to care for a chronically ill partner. Others worry that marriage or cohabitation might alter a gratifying emotional bond, so they sustain the status quo (Koren, 2014; Malta & Farquharson, 2014). The reflections of these couples indicate that at least one partner feels that physical distance is vital for preserving emotional closeness.

## Widowhood

Walt died shortly after Ruth turned 80. Ruth, like the majority of widowed aging adults, described the loss of her spouse as the most stressful event of her life. Being widowed means losing

“the role and identity of being a spouse” (being married and doing things as a couple), which is “potentially one of the most pervasive, intense, intimate, and personal roles” in life (Lund & Caserta, 2004, p. 29). Ruth felt lonely, anxious, and depressed for several months after the funeral.

Because women live longer than men and are less likely to remarry, 34 percent of U.S. women age 65 and older are widowed, compared with just 12 percent of men. At the same time, widowhood rates have declined over the past several decades as divorce among aging adults rose (Mather, Jacobsen, & Pollard, 2015). Ethnic minorities with high rates of poverty and chronic disease are more likely to be widowed.

Earlier we mentioned that most widows and widowers live alone rather than in extended families, a trend that is stronger for whites than for ethnic minorities. Though less well-off financially than married aging adults, most want to retain control over their time and living space and to avoid disagreements with their adult children. Widowed older people who relocate usually move closer to family but not into the same residence.

The greatest problem for recently widowed older people is profound loneliness (Connidis, 2010). But adaptation varies widely. Aging adults have fewer lasting problems than younger individuals who are widowed, probably because death in later life is viewed as less unfair (Bennett & Soulsby, 2012). And most widowed older people—especially those with outgoing personalities and high self-esteem—are resilient in the face of loneliness (Moore & Stratton, 2002; van Baarsen, 2002). To sustain continuity with their past, they try to preserve social relationships that were important before the spouse's death. Social support is vital for favorable adjustment: Greater ease of contact with family and friends, and satisfaction with the support they provide, are associated with a reduction in symptoms of grief and depression and higher sense of self-efficacy in handling tasks of daily living (de Vries et al., 2014).

ICTOR/GETTY IMAGES

Men are less prepared than women for the challenges of widowhood, in part because most relied on their wives for household tasks. This widower has learned to cook—a skill likely to help him connect socially and adapt favorably to his dramatically changed life circumstances.

## Applying what we Know

### Fostering Adaptation to Widowhood in Late Adulthood

SUGGESTION	DESCRIPTION
<b>Self</b> Mastery of new skills of daily living	Especially for men, learning how to perform household tasks such as shopping and cooking, to sustain existing family and friendship ties, and to build new relationships is vital for positive adaptation.
<b>Family and Friends</b> Social support and interaction	Social support and interaction must extend beyond the grieving period to ongoing assistance and caring relationships. Family members and friends can help most by making support available while encouraging the widowed older adult to use effective coping strategies.
<b>Community</b> Senior centers	Senior centers offer communal meals and other social activities, enabling widowed and other older adults to connect with people in similar circumstances and to gain access to other community resources.
Support groups	Support groups can be found in senior centers, religious institutions, and other agencies. Besides new relationships, they offer an accepting atmosphere for coming to terms with loss, effective role models, and assistance with developing skills for daily living.
Religious activities	Involvement in a religious institution can help relieve the loneliness associated with loss of a spouse and offer social support, new relationships, and meaningful roles.
Volunteer activities	One of the best ways for widowed older adults to find meaningful roles is through volunteer activities. Some are sponsored by formal service organizations, such as the Red Cross or the U.S. Senior Corps. Other volunteer programs exist in hospitals, senior centers, schools, and charitable organizations.

Widowed individuals must reorganize their lives, reconstructing an identity that is separate from the deceased spouse. Wives who depended on their husbands for home maintenance and financial decision making typically find this harder than those who were not dependent (Carr et al., 2000). But overall, men show more physical and mental health problems and greater risk of mortality than women, especially when the death was unexpected (Shor et al., 2012; Sullivan & Fenelon, 2014). First, because most men relied on their wives for social connectedness, household tasks, promotion of healthy behaviors, and coping with stressors, they are less prepared than women for the challenges of widowhood. A wife's sudden death heightens this unpreparedness. Second, gender-role expectations lead men to feel less free to express their emotions or to ask for help with meals, housework, and social relationships (Bennett, 2007). Finally, men tend to be less involved in religious activities—a vital source of social support and inner strength.

African-American widowers, however, show no elevated risk of mortality over their married agemates, and they report less depression than European-American widowers (Elwert & Christakis, 2006). Perhaps greater support from extended family and religious community is responsible.

Gender differences in the experience of widowhood contribute to men's higher remarriage rate. Women's kinkeeper role (see Chapter 16, page 552) and ability to form close friendships may lead them to feel less need to remarry. In addition, because many women share the widowed state, they probably offer one another helpful advice and sympathy. In contrast, men often lack skills for maintaining family relationships, forming emotionally

satisfying ties outside marriage, and handling the chores of their deceased wives.

Still, most widowed older adults fare well within a few years, resembling their married counterparts in psychological well-being. Older widows and widowers who participated in several months of weekly classes providing information and support in acquiring daily living skills felt better prepared to manage the challenges of widowed life (Caserta, Lund, & Obrey, 2004). Those who emerge from this traumatic event with a sense of purpose in life and with confidence in their ability to meet everyday challenges often experience stress-related personal growth (Caserta et al., 2009). Many report a newfound sense of inner strength, greater appreciation of close relationships, and reevaluation of life priorities. Applying What We Know above suggests a variety of ways to foster adaptation to widowhood in late adulthood.

### Never-Married, Childless Older Adults

About 5 percent of older Americans have remained unmarried and childless throughout their lives (Mather, Jacobsen, & Pollard, 2015). Almost all are conscious of being different from the norm, but most have developed alternative meaningful relationships. Ruth's sister Ida, for example, formed a strong bond with a neighbor's son. In his childhood, she provided emotional support and financial assistance, which helped him overcome a stressful home life. He included Ida in family events and visited her regularly until she died. Other nonmarried aging adults speak of the centrality of extended family and of younger people in their social networks—often nieces and nephews—and of

©SYRACUSE NEWSPAPERS/L. LONG/THE IMAGE WORKS

As part of a community service project, an older adult collaborates with her nephew in planting flowers at a local park. Never-married, childless older people, especially women, typically lead socially satisfying lives.

influencing them in enduring ways (Wenger, 2009). In addition, same-sex friendships are key in never-married older women's lives (McDill, Hall, & Turell, 2006). These tend to be unusually close and often involve joint travel, periods of coresidence, and associations with each other's extended families.

Never-married, childless men, who are fewer in number than never-married, childless women, are at increased risk for loneliness and depression. And without pressure from a partner to maintain a healthy lifestyle, these men engage in more unhealthy behaviors. Hence, their physical and mental health tends to be less favorable than their married counterparts' (Kendig et al., 2007). But overall, never-married older people report a level of social connectedness and psychological well-being equivalent to that of married aging adults (Hank & Wagner, 2013). These findings hold across various cohorts and Western nations.

Because friendships are not the same as blood ties when it comes to caregiving, being unmarried and childless in very old age reduces the likelihood of informal personal care (Chang, Wilber, & Silverstein, 2010; Wenger, 2009). And with close ties weighted toward friends, nonmarried childless individuals lose more network members with increasing age (Dykstra, 2006). Still, most say that some informal support is available.

## Siblings

The majority of Americans age 65 and older have at least one living sibling. Typically, aging siblings live within 100 miles of each other, communicate regularly, and visit at least several times a year. Both men and women describe closer bonds with sisters than with brothers. Perhaps because of women's greater emotional expressiveness and nurturance, the closer the tie to a sister, the higher older people's psychological well-being (Van Volkom, 2006).

Aging siblings in industrialized nations are more likely to socialize than to provide each other with direct assistance because most older adults turn first to their spouse and children. Nevertheless, siblings seem to be an important "insurance policy" in late

adulthood. After age 70, exchanges of support rise between siblings with a warm relationship (Bedford & Avioli, 2016). Widowed and never-married older people have more contacts with siblings, perhaps because of fewer competing family relationships, and they also are more likely to receive sibling support when their health declines (Connidis, 2010). For example, when Ida's Alzheimer's symptoms worsened, Ruth came to her aid. Although Ida had many friends, Ruth was her only living relative.

## Friendships

As family responsibilities and vocational pressures lessen, friendships take on increasing importance. Having friends is an especially strong predictor of positive emotion and life satisfaction in late adulthood. Older adults report more favorable experiences with friends than with family members, in part because of the pleasurable leisure activities shared with friends (Huxhold, Miche, & Schüz, 2014; Rawlins, 2004). Unique qualities of friendship interaction—openness, spontaneity, mutual caring, and common interests—are also influential.

**Functions of Late-Life Friendships.** The diverse functions of friendship in late adulthood clarify its profound significance:

- *Intimacy and companionship are basic to meaningful late-life friendships.* As Ida and her best friend, Rosie, took walks, went shopping, or visited each other, they disclosed their deepest sources of happiness and worry, engaged in enjoyable conversation, laughed, and had fun. Older adults' descriptions of their close friendships reveal that mutual interests, feelings of belongingness, and opportunities to confide in each other sustain these bonds over time (Field, 1999).
- *Late-life friends help shield each other from negative judgments stemming from stereotypes of aging.* "Where's your cane, Rosie?" Ida asked when the two women were about to leave for a restaurant. "Come on, don't be self-conscious!" Ida reminded Rosie that in the Greek village where her mother grew up, there was no separation between generations, so young people got used to wrinkled skin and weak knees. In fact, older women—as midwives, matchmakers, and experts in herbal medicine, for example—were regarded as the wise ones (Deveson, 1994).
- *Friendships link aging adults to the larger community.* For those unable to go out as often, interactions with friends can keep them abreast of events in the wider world. "Rosie," Ida reported, "did you know there's going to be a new branch of the public library in the train station, and the city council is voting on the living-wage act tonight?" Friends can also open up new experiences, such as travel or participation in community activities.
- *Friendships help protect older adults from the psychological consequences of loss.* Older people in declining health who remain in contact with friends through phone calls and visits show improved psychological well-being (Fiori, Smith, & Antonucci, 2007). Similarly, when close relatives die, friends offer compensating social supports.

**Characteristics of Late-Life Friendships.** Although friendship formation continues throughout life, aging adults prefer familiar, established relationships over new ones. Ties to old and dear friends who live far away are maintained, with growing numbers of older people staying in touch with the aid of e-mail and social media sites, such as Facebook (see page 605 in Chapter 17). With age, the friends they interact with most and feel closest to live in the same community. Similarly, Facebook social networks narrow, containing a greater percentage of individuals considered to be actual friends—people with whom aging adults have a stronger offline connection (Chang et al., 2015). These changes are consistent with socioemotional selectivity theory.

As in earlier years, older people tend to choose friends whose age, sex, ethnicity, and values resemble their own. Compared with younger people, fewer report other-sex friendships. But some have them—usually long-standing ones dating back several decades. Aging adults continue to benefit uniquely from these ties, obtaining an insider’s view of the thoughts, feelings, and behavior of members of the other sex (Monsour, 2002). As agemates die, the very old report more intergenerational friends—both same- and other-sex (Johnson & Troll, 1994). In her eighties, Ruth spent time with Margaret, a 55-year-old widow she met while serving on the board of an adoption agency. Two or three times a month, Margaret came to Ruth’s home for tea and lively conversation.

Gender differences in friendship extend into late adulthood. Women are more likely to have intimate friends; men depend on their wives and, to a lesser extent, their sisters for warm, open communication (Waite & Das, 2013). Also, older women have more **secondary friends**—people who are not intimates but with whom they spend time occasionally, such as a group that meets for lunch, bridge, or museum tours (Blieszner & Roberto, 2012). Through these associates, older adults meet new people, remain socially involved, and gain in psychological well-being.

FSG/ROBERT HARDING

On a village street in Cyprus, these older adults meet often to play backgammon. Spending time with friends they know well who live in the same community is especially gratifying.

In late-life friendships, affection and emotional support are both given and received to maintain balance in the relationship. Although friends call on each other for help with tasks of daily living, they generally do so only in emergencies or for occasional, limited assistance. Aging adults with physical limitations whose social networks consist mainly of friends and who therefore must frequently rely on them for help tend to report low psychological well-being (Fiori, Smith, & Antonucci, 2007). Feelings of excessive dependency and of being unable to reciprocate are probably responsible.

## Relationships with Adult Children

About 80 percent of older adults in Western nations are parents of living children, most of whom are middle-aged. In Chapter 16, we noted that exchanges of help vary with the closeness of the parent–child bond and the needs of the parent and adult child. Recall, also, that over time, parent-to-child help declines, whereas child-to-parent assistance increases.

Aging adults and their adult children are often in touch, even when they live at a distance. But as with other ties, quality rather than quantity of interaction affects older parents’ life satisfaction. In diverse ethnic groups and cultures, warm bonds with adult children reduce the negative impact of physical impairments and other losses (such as death of a spouse) on psychological well-being. And adult children who live nearby and therefore have more face-to-face contact can add substantially to the life satisfaction of aging adults, especially those living alone (Ajrouch, 2007; Milkie, Bierman, & Schieman, 2008; van der Pers, Mulder, & Steverink, 2015). Alternatively, conflict or unhappiness with adult children contributes to poor physical and mental health.

Although aging parents and adult children in Western nations provide each other with various forms of help, level of assistance is typically modest. Older adults in their sixties and seventies—especially those who own their own home and who are married or widowed as opposed to divorced—are more likely to be providers than recipients of help, suggesting SES variations in the balance of support (Grundy, 2005). This balance shifts as older adults age, but well into late adulthood, individuals in Western nations give more than they receive, especially in financial support but also in practical assistance—a circumstance that contradicts stereotypes of older adults as “burdens” on younger generations.

Interviews with parents age 75 and older in five Western nations revealed that in all countries, aid received from adult children most often took the form of emotional support. Fewer than one-third said their children assisted with household chores and errands. Aging parents who provided more help of various kinds than they received scored highest in life satisfaction, those receiving more help than they gave scored lowest, while those in a balanced exchange fell in between (Lowenstein, Katz, & Gur-Yaish, 2007). To avoid dependency, older people usually do not seek children’s practical assistance in the absence of a pressing need, and they express annoyance when children are overprotective or help unnecessarily (Spitze & Gallant, 2004). Moderate support, with many opportunities to reciprocate, is beneficial, fostering self-esteem and sense of family connection.

Gender differences in older parent–adult child interaction are evident. Both mothers and fathers feel ambivalent toward adult offspring with problematic lives—who are financially needy, emotionally troubled, or experiencing marital problems. But mothers are more likely to have adult children who feel similarly ambivalent toward them (Fingerman et al., 2006). Perhaps mothers more often express their mixed feelings.

Cultural expectations can also engender ambivalence. For example, because their high valuing of interdependence among generations meets with challenges in the new society, Cambodian aging immigrants to the United States frequently report ambivalent feelings toward their adult children (Lewis, 2008). And in rural China, where the expectation that sons provide care for their aging parents remains strong, parents harbor more ambivalence toward their rural-residing sons than daughters. Rural sons' greater contact with and support of parents offer myriad opportunities for not living up to expectations! When sons of rural parents move to urban areas, parental ambivalence declines (Guo, Chi, & Silverstein, 2013). Urban residence is associated with more prestigious and secure jobs, perhaps fulfilling rural parents' higher expectations for sons' success and, thus, overcoming shortcomings in providing care.

Feelings of ambivalence undermine the psychological well-being of both adult children and their aging parents (Fingerman et al., 2008). But aging parents' ambivalence toward children is typically mild. Consistent with socioemotional selectivity theory, older parents do their best to accentuate positive emotion.

As social networks shrink in size, relationships with adult children become more important sources of family involvement. People 85 years and older with children have substantially more contacts with relatives than do those without children (Hooymann, Kawamoto, & Kiyak, 2015). Why is this so? Consider Ruth, whose daughter Sybil linked her to grandchildren, great-grandchildren, and relatives by marriage. When childless adults reach their eighties, siblings, other same-age relatives, and close friends may have become frail or died and hence may no longer be available as companions.

## Relationships with Adult Grandchildren

Older people with adult grandchildren and great-grandchildren benefit from a wider potential network of support. Ruth and Walt saw their granddaughter, Marci, and their great-grandson, Jamel, at family gatherings. In between, they occasionally Skyped and regularly used Facebook to keep up with Marci and Jamel's activities. Staying in touch with grandchildren and other family members is the primary reason aging adults say they use social media sites (Zickuhr & Madden, 2012).

In developed nations, slightly more than half of adults over age 65 have a grandchild who is at least 18 years old. In the few studies available on grandparent–adult grandchild relationships, the overwhelming majority of grandchildren say their grandparents positively influenced their values and behavior, and most also expressed an obligation to assist grandparents in need (Even-Zohar, 2011; Fruhauf, Jarrott, & Allen, 2006). Grandparents expect affection (but not practical help) from grandchildren, and

© DAVE LABELLE/THE IMAGE WORKS

A bride and groom take time to express their affection for the bride's grandmother on their wedding day. Grandparents view adult grandchildren as a vital link between themselves and the future.

they usually receive it. They regard the adult grandchild tie as very gratifying—a vital link between themselves and the future.

Still, grandparent–adult grandchild relationships vary greatly. Degree of grandparent involvement during childhood strongly predicts current relationship quality. Often, the tie with one grandchild is “special,” characterized by more frequent contact, affection, and enjoyable times together—factors that enhance older adults' psychological well-being (Mahne & Huxhold, 2015). Relationships with grandmothers tend to be closer, with maternal grandmother–granddaughter bonds the closest, as was so when grandchildren were younger (Sheehan & Petrovic, 2008). However, as grandparents and grandchildren move through life, contact declines. Many grandchildren establish distant homes and become immersed in work, family, and friendship roles that compete for their time.

### LOOK and LISTEN

Interview one or two older people with adult grandchildren about the quality and personal meaning of those relationships.

But despite less contact, grandparents' affection for their adult grandchildren strengthens with age, usually exceeding grandchildren's expressed closeness toward their grandparents (which is still strong) (Harwood, 2001). This difference in emotional investment reflects each generation's needs and goals—adult grandchildren in establishing independent lives, grandparents in preserving family relationships and continuity of values across generations. Grandchildren become increasingly important sources of emotional meaning in the last decade or two of life.

## Elder Maltreatment

Although the majority of older adults enjoy positive relationships with family members, friends, and professional caregivers, some suffer maltreatment at the hands of these individuals. Through media attention, elder maltreatment has become a serious public concern.

Reports from many industrialized nations reveal widely varying rates of maltreatment, from 3 to 28 percent in general population studies. At least 10 percent of U.S. older adults say they were targets during the past year, amounting to over 4 million victims. Elder maltreatment occurs at similar rates across U.S. ethnic groups (Hernandez-Tejada et al., 2013; Roberto, 2016b). All figures are substantial underestimates because most abusive acts take place in private, and victims are often unable or unwilling to complain.

Elder maltreatment usually takes the following forms:

- *Physical abuse.* Intentional infliction of pain, discomfort, or injury, through hitting, cutting, burning, physical force, restraint, or other physically aggressive acts
- *Physical neglect.* Intentional or unintentional failure to fulfill caregiving obligations, resulting in lack of food, medication, or health services or in the older person being left alone or isolated
- *Emotional abuse.* Verbal assaults (such as name calling), humiliation (being treated as a child), and intimidation (threats of isolation or placement in a nursing home)
- *Sexual abuse.* Unwanted sexual contact of any kind
- *Financial abuse.* Illegal or improper exploitation of the aging person's property or financial resources, through theft or use without consent

Emotional abuse, financial abuse, and neglect are the most frequently reported types. Often several forms occur in combination (Kaplan & Pillemer, 2015). The perpetrator is usually a person the older adult trusts and depends on for care and assistance.

Most abusers are family members—spouses (more often men), children of both sexes, and other relatives. Others are friends, neighbors, and people whom aging adults rely on for help and services, such as in-home caregivers and investment counselors (Roberto, 2016a). Abuse in nursing homes is a major concern: From 6 to 40 percent of caregivers admit to having committed at least one act in the previous year (Schiamberg et al., 2011).

Frail aging adults are at high risk for elder maltreatment. Regular home visitors like this nurse can relieve social isolation and help older people take steps to avoid further harm.

Over the past several decades, another form of neglect—referred to in the media as “granny dumping”—has risen: abandonment of older adults with severe disabilities by family caregivers, usually at hospital emergency rooms (Phelan, 2013). Overwhelmed, their caregivers seem to have concluded that they have no other option but to take this drastic step. (See page 557 in Chapter 16 and pages 592–593 in Chapter 17 for related research.)

**Risk Factors.** Characteristics of the victim, the abuser, their relationship, and its social context are related to the incidence and severity of elder maltreatment. The more risk factors present, the greater the likelihood that abuse and neglect will occur.

**Dependency of Victims.** Very old, frail, and mentally and physically impaired older adults are more vulnerable to maltreatment, with as many as 25 percent affected (Dong et al., 2011; Selwood & Cooper, 2009). This does not mean that declines in functioning cause abuse. Rather, when other conditions are ripe for maltreatment, older people with severe disabilities are least able to protect themselves. Those with physical or cognitive impairments may also have personality traits that make them vulnerable—a tendency to lash out when angry or frustrated, a passive or avoidant approach to handling problems, and a low sense of self-efficacy (Salari, 2011). The more negative a caregiver–recipient relationship, the greater the risk of elder abuse of all kinds, particularly when that relationship has a long unfavorable history.

**Dependency of Perpetrators.** Within late-life parent–child relationships especially, abusers are often dependent, financially or emotionally, on their victims. This dependency, experienced as powerlessness, can lead to aggressive, exploitative behavior. Often the perpetrator–victim relationship is one of mutual dependency (Jackson & Hafemeister, 2012). The adult-child abuser needs the aging parent for money, housing, or emotional support, and the aging parent needs the abuser for assistance with everyday tasks or to relieve loneliness.

**Psychological Disturbance and Other Traits of Perpetrators.** Salient factors underlying the dependency of abusive adult children are mental illness and alcohol or other drug addictions (Jogerst et al., 2012). Often these perpetrators are socially isolated, have difficulties at work, or are unemployed, with resulting financial worries. These factors increase the likelihood that they will lash out when caregiving is highly demanding or the behavior of an older adult with dementia is irritating or hard to manage.

Abusers who are paid caregivers or professionals rendering other services are usually amiable but manipulative, on the lookout for opportunities to take advantage of older adults, especially those with cognitive declines (Lichtenberg, 2016). Perpetrators may overcharge, scam, or have access to financial accounts or valuables. When opportunities arise, they steal from the victim.

**History of Family Violence.** Elder abuse by family members is often part of a long history of family violence. Adults who were abused as children are at increased risk of abusing older adults

(Reay & Browne, 2008). In Chapter 8, we showed how aggressive cycles between family members can easily become self-sustaining, leading to the development of individuals who cope with anger through hostility toward others. In many instances, elder abuse is an extension of years of partner abuse (Walsh et al., 2007).

**Institutional Conditions.** Elder maltreatment is more likely to occur in nursing homes that are rundown and overcrowded and that have staff shortages, minimal staff supervision, high staff turnover, and few visitors (Schiamberg et al., 2011). Highly stressful work conditions combined with minimal oversight of caregiving quality set the stage for abuse and neglect.

**Consequences of Elder Maltreatment.** All forms of elder maltreatment have profound, lasting consequences on victims' health and adjustment. Persisting anxiety, depression, post-traumatic stress symptoms, and heightened physical and cognitive impairments are common outcomes (Roberto, 2016a). Consequently, victims are at risk for premature institutionalization and shortened survival.

Financial exploitation deprives older Americans of an estimated three billion dollars annually (MetLife, 2011b). It may engender family disputes, reduced health-care options, and declining mental health.

**Preventing Elder Maltreatment.** Preventing elder maltreatment by family members is especially challenging. Victims may fear retribution, wish to protect abusers who are spouses or adult children, or feel embarrassed that they cannot control the situation. And they may be intimidated into silence or not know where to turn for help (Roberto et al., 2015). Once abuse is discovered, intervention involves immediate protection and provision of unmet needs for the older adult and of mental health services and social support for the spouse or caregiver.

Prevention programs offer caregivers counseling, education, and respite services, such as day care and in-home help for aging adults. Trained volunteer “buddies” who make visits to the home can relieve social isolation and assist older people with problem solving to avoid further harm. Support groups help them identify abusive acts, practice appropriate responses, and form new relationships. And agencies that provide informal financial services to older people who are unable to manage on their own, such as writing and cashing checks and holding valuables in a safe, reduce financial abuse.

When elder abuse is extreme, legal action offers the best protection, yet it is rare. Many victims are reluctant to initiate court procedures or, because of mental impairments, cannot do so. In these instances, social service professionals must induce caregivers to rethink their role and assist in finding alternatives. In nursing homes, improving staff selection, training, and working conditions can greatly reduce abuse and neglect.

### LOOK and LISTEN

Contact your state's department on aging. Find out about its policies and programs aimed at preventing elder abuse.

Combating elder maltreatment also requires efforts at the level of the larger society, including public education to encourage reporting of suspected cases and improved understanding of the needs of older people. As part of this effort, aging adults benefit from information on where to go for help (National Center on Elder Abuse, 2016). Finally, countering negative stereotypes of aging reduces maltreatment because recognizing older adults' dignity, individuality, and autonomy is incompatible with acts of physical and psychological harm.

## Ask yourself

**CONNECT** Why is adjustment to late-life divorce usually more difficult for women and adjustment to widowhood more difficult for men?

**APPLY** At age 51, Mae lost her job, couldn't afford to pay rent, and moved in with her 78-year-old widowed mother, Beryl. Although Beryl welcomed Mae's companionship, Mae grew depressed, drank heavily, and stopped looking for work. When Beryl complained about Mae's behavior, Mae insulted and slapped her. Explain why this mother–daughter relationship led to elder abuse.

**REFLECT** If you have living grandparents, describe your relationship with one or more of them. How have you and your grandparent contributed to each other's development?

## Retirement

**18.11** Discuss the decision to retire, adjustment to retirement, and involvement in leisure and volunteer activities.

In Chapter 16, we noted that increased life expectancy led the period of retirement to lengthen over the twentieth century. In recent decades, however, age of retirement has risen in the United States and Western nations. The economic recession of 2007 to 2009 extended this trend, modestly raising the retirement age of the baby boomers (see page 563). Irrespective of financial need, however, the majority of baby boomers say they want to work longer, with one-third indicating that devoting some time to work is important for a happy retirement (Mather, Jacobsen, & Pollard, 2015). The distinction between work and retirement has blurred: Nearly 40 percent of U.S. adults age 65 to 69, and nearly 20 percent of those in their seventies, are still working in some capacity—rates anticipated to increase markedly over the next decade.

As these figures suggest, the contemporary retirement process is highly variable: It may include a planning period, the decision itself, diverse acts of retiring, and continuous adjustment and readjustment of activities for the rest of the life course. The majority of U.S. older adults with career jobs retire gradually by cutting down their hours and responsibilities. Many take *bridge jobs* (new part-time jobs or full-time jobs of shorter duration) that serve as transitions between full-time career and retirement (Rudolph & Toomey, 2016). About 15 percent leave their jobs but later return to paid work and even start new careers, desiring to introduce interest and challenge into their lives,

to supplement limited financial resources, or both (Sterns & McQuown, 2015). Today, retirement is not a single event but rather a dynamic process with multiple transitions serving different purposes.

In the following sections, we examine factors that affect the decision to retire, happiness during the retirement years, and leisure and volunteer pursuits. We will see that the process of retirement and retired life reflect an increasingly diverse retired population.

## The Decision to Retire

Walt and Ruth's retirement was preceded by extensive planning (see Chapter 16, pages 562–563), including a projected date for leaving the work force and financial preparation guaranteeing comfortable income-replacement benefits. In contrast, Walt's brother Dick was forced to retire as the operating costs of his bakery rose while his clientele declined. He looked for temporary employment in sales while his wife, Goldie, kept her part-time job as a bookkeeper to help cover living expenses.

Affordability of retirement is usually the first consideration in the decision to retire. Yet despite financial concerns, many preretirees decide to let go of a steady work life in favor of alternative, personally meaningful work, leisure, or volunteer activities. "I had been working since I was 10 years old," said one retired auto worker. "I wanted a rest." Exceptions to this positive outlook are people like Dick—forced into retirement or earning very low wages—who reluctantly take bridge jobs in another field to make ends meet. Bridge employment seems to have a favorable impact on psychological well-being only when people engage in work related to their former career (Wang & Shultz, 2010). Preservation of vocational interests, roles, and expertise is key to older adults taking a phased approach to retirement.

Figure 18.4 summarizes personal and workplace factors that influence the decision to retire. People in good health, for whom vocational life is central to self-esteem, and whose work environments are pleasant and interesting are

likely to keep on working. For these reasons, individuals in high-earning professional occupations usually retire later than those in blue-collar or clerical positions. And when they do retire, they more often shift to stimulating bridge jobs, with some retiring and returning to the work force multiple times (Feldman & Beehr, 2011; Wang, Olson, & Shultz, 2013). Self-employed older adults also work longer, probably because they can flexibly adapt their job's demands to fit their changing capacities and needs (Feldman & Vogel, 2009). In contrast, people in declining health, who are engaged in routine, boring work, who have pleasurable leisure or family pursuits, or who otherwise perceive a decline in the fit of their work with their skills and interests often opt for retirement.

Societal factors also affect retirement decisions. When many younger, less costly workers are available to replace older workers, industries are likely to offer added incentives for people to retire, such as increments to pension plans and earlier benefits—a trend that has, until recently, contributed to many early retirements in Western nations. But when concern increases about the burden on younger generations of an expanding population of retirees, eligibility for retirement benefits may be postponed to a later age. In the United States, for example, the current retirement age of 66 for full Social Security benefits will rise to 67 for individuals born in 1960 or later.

Retirement decisions vary with gender and ethnicity. On average, women retire earlier than men, largely because family events—a spouse's retirement or the need to care for an ill partner or parent—play larger roles in their decisions. However, single women and ethnic minorities, who are overrepresented among older adults in or near poverty, often lack financial resources to retire (Griffin, Loh, & Hesketh, 2013). Many continue working into old age.

In most Western nations, generous social security benefits make retirement feasible for the economically disadvantaged and sustain the standard of living of most workers after they retire. The United States is an exception: Many U.S. retirees, especially those who held low-income jobs without benefits, experience

**FIGURE 18.4** Personal and workplace factors that influence the decision to retire.

falling living standards. Denmark, France, Germany, Finland, and Sweden have gradual retirement programs in which older employees reduce their work hours, receive a partial pension to make up income loss, and continue to accrue pension benefits. Besides strengthening financial security, this approach introduces a transitional phase that fosters retirement planning and well-being (Peiró, Tordera, & Potocnik, 2012). And some countries' retirement policies are sensitive to women's more interrupted work lives. In Canada, France, and Germany, for example, time devoted to child rearing is given some credit when figuring retirement benefits.

In sum, individual preferences shape retirement decisions. At the same time, older adults' opportunities and limitations greatly affect their choices.

## Adjustment to Retirement

Because retirement involves giving up roles that are a vital part of identity and self-esteem, it is often assumed to be a stressful process that contributes to declines in physical and mental health. Consider Dick, who reacted to the closing of his bakery with anxiety and depression. His adjustment difficulties resemble those of younger people experiencing job loss (see Chapter 16, page 562). But recall that Dick had a cranky, disagreeable personality. In this respect, his psychological well-being after retirement was similar to what it had been before!

We must be careful not to assume a cause-and-effect relationship each time retirement is paired with unfavorable reactions. For example, a wealth of evidence confirms that physical health problems lead older adults to retire, rather than the reverse (Shultz & Wang, 2007). And for most people, mental health and perceived quality of life are fairly stable from the pre- to postretirement years, with little change prompted by retirement itself. The widely held belief that retirement inevitably leads to adjustment problems is contradicted by countless research findings indicating that most people adapt well. Contemporary older people view retirement as a time of opportunity and personal growth and describe themselves as active and socially involved—major determinants of retirement satisfaction (Salami, 2010; Wang & Shultz, 2010). Still, about 10 to 30 percent mention some adjustment difficulties.

Workplace factors—especially financial worries and having to give up one's job—predict stress following retirement. Pressures at work also make a difference. Moving out of a high-stress job is associated with gains in psychological well-being following retirement, whereas leaving a pleasant, low-stress job or a highly satisfying job before one is ready is linked to greater difficulties during the retirement transition, typically followed by recovery (Wang, 2007). And especially for women, who take on greater caregiving responsibilities, retirement may not relieve the stress of family burdens (Coursolle et al., 2010). Rather, it may reduce work-based avenues of personal satisfaction, thereby triggering depressive symptoms and poorer psychological well-being.

Among psychological factors, a sense of personal control over life events, including deciding to retire for internally motivated reasons (to do other things), is strongly linked to retirement satisfaction (Kubicek et al., 2011; van Solinge, 2013). At the same

time, those who find it hard to give up the predictable schedule and social contacts of the work setting or who have few nonwork social ties experience discomfort. Overall, however, well-educated people with complex jobs adjust more favorably (Kim & Moen, 2002). Perhaps the satisfactions derived from challenging, meaningful work readily transfer to nonwork pursuits.

As with other major life events, social support reduces stress associated with retirement. Although social network size typically shrinks as relationships with co-workers decline, quality of relationships remains fairly stable for most people. And many add to their social networks through leisure and volunteer pursuits (Kloep & Hendry, 2007). In Dick's case, entering a life-care community eased a difficult postretirement period, leading to new friends and rewarding leisure activities, some of which he shared with Goldie.

Finally, marital happiness generally fosters a favorable retirement transition. When a couple's relationship is positive, it can buffer the uncertainty of retirement. And retirement can enhance marital satisfaction by granting happily married couples more time for companionship (van Solinge & Henkens, 2008; Wang, 2007). Marital dissatisfaction, in contrast, interferes with retirement adjustment, in part because it heightens exposure to an unhappy relationship.

In line with continuity theory, people try to sustain gratifying lifestyle patterns, self-esteem, and values following retirement and, in favorable economic and social contexts, usually succeed. Return to Chapter 16, page 563, for ways adults can plan ahead to increase the chances of a positive transition to retirement.

## Leisure and Volunteer Activities

With retirement, most older adults have more time for leisure and volunteer activities than ever before. After a "honeymoon period" of trying out new options, many discover that interests and skills do not develop suddenly. Instead, meaningful leisure and community service pursuits are usually formed earlier and sustained or expanded during retirement (Pinquart & Schindler, 2009). For example, Walt's fondness for writing, theater, and gardening dated back to his youth. And Ruth's strong focus on her social work career led her to become an avid community volunteer.

Involvement in leisure activities and, especially, volunteer service is related to better physical and mental health and reduced mortality (Cutler, Hendricks, & O'Neill, 2011). But simply participating does not explain this relationship. Instead, older adults select these pursuits because they permit self-expression, new achievements, the rewards of helping others, pleasurable social interaction, and a structured daily life. And those high in sense of self-efficacy are more engaged (Diehl & Berg, 2007). These factors account for gains in well-being.

As mobility limitations increase, the frequency and variety of leisure pursuits tend to decline, with activities increasingly becoming less strenuous (Dorfman, 2016). Older adults in residential communities participate more than those in ordinary homes because activities are conveniently available. But regardless of living arrangements, aging adults choose activities not for convenience but rather on the basis of whether they are personally gratifying.

© MARJORIE KAMYS COTERA/THE IMAGE WORKS

Time devoted to volunteering is higher in late adulthood than at any other time of life. This Red Cross disaster-relief volunteer traveled to Texas to provide medical assistance to victims of a fertilizer plant explosion.

Older people contribute enormously to society through volunteer work, a trend that is strengthening. About one-third of those in their sixties and seventies in industrialized nations report volunteering. Of those who do, over half give 200 or more hours per year (HSBC & Oxford Institute of Ageing, 2007; U.S. Bureau of Labor Statistics, 2016). Younger, better-educated, and financially secure older adults with social interests are more likely to volunteer, women more often than men. Although most extend an earlier pattern of civic engagement, nonvolunteers are especially receptive to volunteer activities in the first few years after retiring as they look for ways to compensate for work-role losses (Mutchler, Burr, & Caro, 2003). The retirement transition is a prime time to recruit older people into these personally rewarding, socially useful pursuits.

### LOOK and LISTEN

Interview an older adult participating in a significant community service role about the personal meaning of the experience at this time of life.

Volunteering grants older adults a continuing sense of making valuable contributions to society, and most sustain high commitment through their seventies. In a survey of a large, nationally representative U.S. sample, time spent volunteering rose steadily over adulthood, not declining until the eighties (Hendricks & Cutler, 2004). Even then, it remained higher than at any other period of life! In accord with socioemotional selectivity theory, older people eventually narrow their volunteering to fewer roles, concentrating on one or two that mean the most to them (Windsor, Anstey, & Rodgers, 2008). They seem to recognize that excessive volunteering reduces its emotional rewards and, therefore, its benefits. See the Biology and Environment box on page 638 to find out about an innovative service program that has impressive effects on older adults' physical, cognitive, and social functioning while also enhancing children's academic success.

Finally, when Walt and Ruth got together with Dick and Goldie, the two couples often discussed politics. Older adults report greater awareness of and interest in public affairs and typically vote at a higher rate than any other age group. Even in late old age, political knowledge shows no sign of decline. After retiring, they have more time to keep abreast of current events. They also have a major stake in debates over policies central to their welfare. But older adults' political concerns are far broader than those that serve their own age group, and their voting behavior is not driven merely by self-interest (Campbell & Binstock, 2011). Rather, their political involvement may stem from a deep desire for a safer, more secure world for future generations.

## Successful Aging

**18.12** Discuss the meaning of successful aging.

Walt, Ruth, Dick, Goldie, and Ida, and the research findings they illustrate, reveal great diversity in development during the final decades of life. Walt and Ruth fit contemporary experts' view of **successful aging**, in which gains are maximized and losses minimized, enabling realization of individual potential. Both were actively engaged with their families and communities, coped well with negative life changes, enjoyed a happy intimate partnership and other close relationships, and led daily lives filled with gratifying activities. Ida, too, aged successfully until the onset of Alzheimer's symptoms overwhelmed her ability to manage life's challenges. As a single adult, she built a rich social network that sustained her into old age. In contrast, Dick and Goldie reacted with despondency to physical aging and other losses (such as Dick's forced retirement). And Dick's angry outbursts restricted their social contacts, although the couple's move to a life-care community eventually led to an improved social life.

People age well when their growth, vitality, and strivings limit and, at times, overcome physical, cognitive, and social declines. Researchers want to know more about factors that contribute to successful aging so they can help more people experience it. Yet theorists disagree on the precise ingredients of a satisfying old age. Some focus on easily measurable outcomes, such as excellent cardiovascular functioning, absence of disability, superior cognitive performance, and creative achievements. But this view has been heavily criticized (Brown, 2016a). Not everyone can become an outstanding athlete, an innovative scientist, or a talented artist. And many older adults do not want to keep on accomplishing and producing—the main markers of success in Western nations. Each of us is limited by our genetic potential as it combines with a lifetime of environments we encounter and select for ourselves. Furthermore, outcomes valued in one culture may not be valued in others.

Perspectives on successful aging have turned away from specific achievements toward processes people use to reach personally valued goals (Freund & Baltes, 1998; Kahana et al., 2005; Lang, Rohr, & Williger, 2011). Instead of identifying one set of

## Biology and Environment

### Experience Corps: Promoting Retired Adults' Physical and Mental Health and Children's Academic Success

**E**xperience Corps is an innovative, community-based intergenerational intervention aimed at slowing biological aging and enhancing the well-being of retired adults while also strengthening the academic success of kindergarten through third-grade children (Rebok et al., 2014). To attain maximum impact, the program is intensive and stimulating, for retirees and children alike.

Volunteers join teams of 7 to 10 for a rigorous 30-hour training program, where they acquire skills in tutoring and behavior management of children. Teams are then placed in low-income inner-city schools, where each volunteer devotes at least 15 hours per week throughout the school year to helping students identified by their teachers as in need of academic support. Teams meet at least every two weeks for problem solving and refresher training, to enhance impact on children while also fostering a sense of community among volunteers.

Currently, Experience Corps has nearly 3,000 volunteers working in 22 U.S. cities. How effective is it in attaining its intergenerational goals?

To find out, several hundred adults age 60 and older were randomly assigned to the program in the Baltimore, New York, and Port Arthur, Texas, public schools or to a wait-list control group. Outcomes were impressive: Schools where children received Experience

Corps tutoring and mentoring showed higher end-of-year reading achievement and a reduction in disruptive classroom behavior, relative to other schools with similar student bodies (Gattis et al., 2010; Lee et al., 2012).

Simultaneously, older adults benefitted in wide-ranging ways, in Baltimore and in an expanded evaluation carried out in 17 U.S. cities. After 4 to 8 months of service, volunteers reported gains in physical activity and strength, whereas controls reported declines (Fried et al., 2004). And after two years of service, program participants indicated fewer physical limitations and depressive symptoms relative to controls (Hong & Morrill-Howell, 2010). From serving on teams and connecting with school personnel, volunteers also reported enhanced social support.

Furthermore, in studies addressing neurobiological outcomes, Experience Corps volunteers, but not controls, showed changes in fMRI brain activity over a school year that coincided with gains in executive function. And two years of program participation was associated with mild gains in size of the cerebral cortex and hippocampus (centrally involved in memory), whereas controls declined (Carlson et al.,

COURTESY OF THE AARP FOUNDATION  
EXPERIENCE CORPS, BALTIMORE CITY

Experience Corps provides intensive training to older adult volunteers, who join teams that provide academic support to low-income inner-city schoolchildren. Intergenerational benefits are impressive: Children improve academically and behaviorally, and volunteers gain in physical, cognitive, and social well-being.

2009, 2015). Sustained, physically active and cognitively challenging volunteering appeared to increase the plasticity of brain regions supporting vital late-life cognitive skills.

Experience Corps demonstrates the powerful impact of a “high-dose” volunteer program on aging adults’ physical, cognitive, and social well-being, while also improving children’s academic functioning in ways that forecast life success. Recently, Experience Corps joined forces with AARP, the largest organization for older Americans, with plans to extend the program to many more older adults and children in need.

standards as “successful,” this view focuses on how people minimize losses while maximizing gains. From this vantage point, *optimal aging* might be a better descriptor than the commonly used term *successful aging*. Optimal aging reflects the reality that aging well involves not only achievement of desirable outcomes but also effective coping with life’s challenges and losses.

In research on diverse samples of adults followed over the lifespan, George Vaillant looked at how various life-course factors contributed to late-life physical and psychological well-being (Vaillant & Mukamal, 2001). Findings revealed that factors people can control to some degree (such as health habits, coping strategies, marital stability, and years of education) far outweighed uncontrollable factors (parental SES, family warmth in childhood, early physical health, and longevity of family members) in predicting a satisfying, active old age.

Consider one participant, who in childhood had experienced low SES, parental discord, a depressed mother, and seven siblings crowded into a tenement apartment. Despite these early perils, he became happily married and, through the GI bill, earned an accounting degree. At 70, he was aging well:

Anthony Pirelli may have been *ill* considering his heart attack and open-heart surgery, but he did not feel *sick*. He was as physically active as ever, and he continued to play tennis. Asked what he missed about his work, he exulted, “I’m so busy doing other things that I don’t have time to miss work. . . . Life is not boring for me.” He did not smoke or abuse alcohol; he loved his wife; he used mature [coping strategies]; he obtained 14 years of education; he watched his waistline; and he exercised regularly. (Adapted from Vaillant, 2002, pp. 12, 305.)

Vaillant concluded, “The past often predicts but never determines our old age” (p. 12). Successful aging is an expression of remarkable resilience during this final period of the lifespan.

In this and the previous chapter, we have considered many ways that older adults realize their goals. Look back and review the most important ones:

- Optimism and sense of self-efficacy in improving health and physical functioning (page 581)
- Selective optimization with compensation to make the most of limited physical energies and cognitive resources (pages 595 and 616)
- Strengthening of self-concept, which promotes self-acceptance and pursuit of hoped-for possible selves (pages 612–614)
- Enhanced emotional self-regulation and emotional positivity, which support meaningful, rewarding social ties (pages 611–612)
- Acceptance of change, which contributes to effective coping and life satisfaction (page 614)
- A mature sense of spirituality and faith, permitting anticipation of death with calm composure (pages 614–615)
- Personal control over domains of dependency and independence, enabling investment in self-chosen, highly valued activities (pages 616, 618)
- High-quality relationships, which offer pleasurable companionship and social support (page 622)
- Personally meaningful leisure and volunteer pursuits, which contribute to physical, cognitive, and social well-being (pages 636–637)

Aging well is facilitated by societal contexts that promote effective person–environment fit, enabling older people to manage life changes. Older adults need well-funded social security plans, good health care, safe housing, and diverse social services. (See, for example, the description of the U.S. Area Agencies on Aging in Chapter 2, page 65.) Yet because of inadequate funding

and difficulties reaching rural communities, many older adults’ needs remain unmet. Isolated aging adults with little education may not know how to gain access to available assistance. Furthermore, the U.S. Medicare system of sharing health-care costs with older adults strains the financial resources of many. And housing that adjusts to changes in older people’s capacities, permitting them to age in place without disruptive and disorienting moves, is available only to the economically well-off.

Besides improving policies that meet older adults’ basic needs, new future-oriented approaches must prepare for increased aging of the population. More emphasis on lifelong learning for workers of all ages would help people maintain and expand their skills as they grow older. Also, reforms that prepare for expected growth in the number of frail aging adults are vital, including affordable help for family caregivers, adapted housing, and sensitive nursing home care.

All these changes involve recognizing, supporting, and enhancing the contributions that seniors make to society—both the older adults of today and those of tomorrow. A nation that takes care of its aging citizens and grants them a multitude of opportunities for personal growth maximizes the chances that each of us, when our time comes to be old, will age optimally.

## Ask yourself

**CONNECT** Leisure and volunteer interests and skills usually form early and persist over the lifespan. Referring back to earlier parts of this book, cite examples of childhood, adolescent, and early adulthood experiences that are likely to foster meaningful pursuits after retirement.

**APPLY** Provide research-based advice to a couple considering retirement about steps they might take to promote favorable retirement adjustment.

**REFLECT** Think of someone you know who is aging successfully. What personal qualities led you to select that person?

## Summary / chapter 18

### Erikson’s Theory: Ego Integrity versus Despair (p. 610)

**18.1** According to Erikson, how does personality change in late adulthood?

- Erikson’s final psychological conflict, **ego integrity versus despair**, involves coming to terms with one’s life. Adults who arrive at a sense of integrity feel whole and satisfied with their achievements. Despair occurs when older people feel time is too short to find an alternate route to integrity.

### Other Theories of Psychosocial Development in Late Adulthood

(p. 610)

**18.2** Discuss Robert Peck’s and Joan Erikson’s views of psychosocial development in late adulthood, along with implications of the positivity effect and reminiscence for older adults’ lives.

- According to Robert Peck, attaining ego integrity involves three distinct tasks: ego differentiation, body transcendence, and ego transcendence.

- Joan Erikson believes these attainments represent an additional psychosocial stage, **gerotranscendence**, evident in inner calm and quiet reflection. More evidence, however, is needed to confirm this late-life stage.
- Most older people display a **positivity effect**—a bias toward emotionally positive information—likely because they have become expert in emotional self-regulation.

- **Reminiscence** about one's past can be positive and adaptive for older people. But many well-adjusted older adults spend little time seeking greater self-understanding through life review. Rather, as the term **Third Age** conveys, they are largely present- and future-oriented, seeking opportunities for personal fulfillment.

## Stability and Change in Self-Concept and Personality (p. 612)

### 18.3 Cite stable and changing aspects of self-concept and personality, and discuss spirituality and religiosity in late adulthood.

- The “big five” personality traits remain stable from mid- to late life. Older adults' accumulation of a lifetime of self-knowledge leads to more secure, multifaceted self-concepts. Those who continue to actively pursue hoped-for possible selves gain in life satisfaction. A flexible, optimistic approach to life fosters resilience, and engaging in cognitively challenging activities promotes openness to experience.

- While older people generally become more religious or spiritual as they age, this increase is usually modest and is not universal. For many, religiosity is stable throughout adulthood. Faith and spirituality may become more reflective, accepting uncertainty and emphasizing links to others. Religious involvement is especially high among low-SES ethnic minority older people and women and is linked to better physical and psychological well-being and longer survival.

## Contextual Influences on Psychological Well-Being (p. 615)

### 18.4 Discuss the influence of control versus dependency, physical health, negative life changes, and social support on older adults' psychological well-being.

- In patterns of behavior called the **dependency–support script** and the **independence–ignore script**, older adults' dependency behaviors are attended to immediately while their independent behaviors are ignored. But permitting older adults to select areas in which they desire help enables them to use their capacities fully in pursuit of their goals and creates an effective **person–environment fit**, which fosters psychological well-being.

- Physical health is a powerful predictor of late-life psychological well-being. The relationship between physical and mental health problems can become a vicious cycle, each intensifying the other. People age 85 and older have the highest suicide rate of all age groups.

- Although aging adults are at risk for a variety of negative life changes, these events evoke less stress and depression in older than in younger people. But when negative changes pile up, they test older adults' coping resources.

- Social support promotes physical health and psychological well-being, but excessive assistance or help that cannot be returned often interferes with self-efficacy and amplifies psychological stress. Consequently, perceived social support, rather than sheer amount of help, is associated with a positive outlook.

## A Changing Social World (p. 619)

### 18.5 Describe the limitations of disengagement theory and activity theory, and explain the more recent perspectives of continuity theory and socioemotional selectivity theory.

- Disengagement theory holds that mutual withdrawal between older people and society occurs in anticipation of death. Most older adults, however, do not disengage. Activity theory states that social barriers to engagement cause declining rates of interaction. Yet older people with more social contact are not necessarily happier.
- **Continuity theory** proposes that most aging adults strive to maintain consistency between their past and anticipated future. By using familiar skills and engaging in familiar activities with familiar people, older people integrate late-life changes into a coherent, consistent life path.
- **Socioemotional selectivity theory** states that social networks become more selective with age. Older adults, who face a shortened future, emphasize the emotion-regulating function of interaction, preferring high-quality, emotionally fulfilling relationships.

### 18.6 How do communities, neighborhoods, and housing arrangements affect older adults' social lives and adjustment?

- Suburban older adults have higher incomes and report better health than their inner-city counterparts, but the latter benefit from access to public transportation. Small-town and rural aging adults, who are less likely to live near their children, compensate by interacting more with nearby relatives, neighbors, and friends. Living in neighborhoods with like-minded older people promotes life satisfaction.

- Most older people prefer **aging in place**, but for those with health and mobility problems, independent living poses risks, and many older adults who live alone are poverty-stricken.

- Residential settings for older adults who need assisted living include **independent living communities**, which provide a variety of hotel-like support services, and **life-care communities**, which offer a range of housing alternatives guaranteeing that residents' changing needs will be met as they age.

MARK LYONS/THE NEW YORK TIMES/REDUX

- The small number of U.S. older adults living in nursing homes experience extreme restriction of autonomy and low social interaction. Homelike nursing homes that achieve an effective person–environment fit foster late-life well-being.

## Relationships in Late Adulthood

(p. 625)

### 18.7 Describe changes in relationships in late adulthood, including marriage, lesbian and gay partnerships, divorce, remarriage, and widowhood, and discuss never-married, childless older adults.

- The **social convoy** is an influential model of changes in individuals' social networks as they move through life. As ties are lost, aging adults seek ways to maintain gratifying relationships and cultivate new ones, though not as many as they did at younger ages.
- Paths of late-life marital satisfaction are diverse and depend on such factors as shared activities and financial difficulties. Married older people usually have larger social networks linked to psychological well-being and good health.

- Most lesbian and gay older couples also report happy, highly fulfilling relationships. Compared with couples not in a legally recognized relationship, those who are married are advantaged in physical and psychological well-being.

- Divorce in late life brings greater stress than for younger people. Although older adults' remarriage rates are low, those who do remarry enter into more stable relationships. Increasingly, older couples in a new relationship choose cohabitation or "living apart together" as long-term alternatives to marriage.
- Adaptation to widowhood varies widely. Aging adults fare better than younger individuals, and women better than men. Efforts to maintain social ties, an outgoing personality, high self-esteem, and a sense of self-efficacy in handling tasks of daily living promote resilience.
- Most older adults who have remained unmarried and childless throughout their lives develop alternative meaningful relationships. Never-married childless women are better-adjusted than men, but both find social support.

### 18.8 How do sibling relationships and friendships change in late life?

- In late adulthood, aging siblings typically live nearby, communicate regularly, and visit at least several times a year. Especially for widowed and never-married older people, siblings provide an important "insurance policy."

- Late-life friendships serve diverse functions: intimacy and companionship, a shield against negative judgments, a link to the larger community, and protection from the psychological consequences of loss. Older adults prefer established same-sex friendships, and women, more than men, have both intimate friends and **secondary friends**, with whom they spend time occasionally.

### 18.9 Describe older adults' relationships with adult children and adult grandchildren.

- Older adults are often in touch with their adult children, who more often provide emotional support than direct assistance. Aging parents who provide more help than they receive score highest in life satisfaction. Though typically mild, ambivalent feelings toward adult children undermine psychological well-being.
- Older people with adult grandchildren benefit from a wider potential network of support. Grandparents typically expect affection, but not practical help, from grandchildren. Although grandparent–grandchild contact declines over time, grandparents' emotional investment often strengthens.

### 18.10 Discuss elder maltreatment, including risk factors, consequences, and prevention strategies.

- Some older adults suffer maltreatment at the hands of family members, friends, or professional caregivers. Risk factors include a dependent perpetrator–victim relationship, perpetrator psychological disturbance, a history of family violence, and inadequate institutional conditions. All forms of elder maltreatment have profound, lasting consequences on victims' physical and mental health.
- Elder-abuse prevention programs provide counseling, education, and respite services for caregivers. Trained volunteers and support groups can help victims avoid future harm. Societal efforts that encourage reporting of suspected cases and increase understanding of older people's needs are also vital.

## Retirement (p. 634)

### 18.11 Discuss the decision to retire, adjustment to retirement, and involvement in leisure and volunteer activities.

- The decision to retire depends on diverse factors, including affordability, health status, nature of the work environment, opportunities to pursue meaningful activities, gender, ethnicity, and societal retirement policies.

- Factors affecting adjustment to retirement include satisfactions previously derived from work, caregiving responsibilities, a sense of personal control over life events, social support, and marital happiness.
- Meaningful leisure and volunteer pursuits are typically sustained or expanded during retirement. Involvement is related to better physical and mental health and to reduced mortality.

## Successful Aging (p. 637)

### 18.12 Discuss the meaning of successful aging.

- Older adults who experience **successful aging** minimize losses and maximize gains, enabling realization of individual potential. Societal contexts that permit older adults to manage life changes—including well-funded social security plans, good health care, safe housing, diverse social services, and opportunities for lifelong learning—foster aging well.

## Important Terms and Concepts

aging in place (p. 623)

# milestones

## Development in Late Adulthood

REB IMAGES/GETTY IMAGES

- Declines in immune system functioning increase risk for a variety of illnesses, including infectious diseases, cardiovascular disease, certain forms of cancer, and several autoimmune disorders. (577)
- Timing of sleep shifts to earlier bedtime and earlier morning waking; sleep difficulties increase. (577)
- Graying and thinning of the hair continue; the skin wrinkles and sags further and becomes more transparent as it loses its fatty layer of support; “age spots” increase. (578)
- Height and weight decline because of loss of lean body mass. (578)

DON MASON/BLEND IMAGES/GETTY IMAGES

### 65–80 YEARS

#### Physical

- Performance of autonomic nervous system declines, impairing tolerance for extremes of heat and cold. (574)
- Declines in vision continue, with increased sensitivity to glare and impaired color discrimination, dark adaptation, depth perception, and visual acuity. (574–575)
- Declines in hearing continue throughout the frequency range. (575)
- Sensitivity to taste and odor may decline. (576)
- Touch sensitivity declines on the hands, especially the fingertips. (576)
- Declines in cardiovascular and respiratory functioning lead to greater physical stress during exercise. (576–577)

JOHN LUND/MARC ROMANELLI/GETTY IMAGES

- Continued loss of bone mass leads to rising rates of osteoporosis. (578, 585)
- Frequency of sexual activity and intensity of sexual response decline, although most married older adults report regular sexual enjoyment. (583–584)

#### Cognitive

- Processing speed and other aspects of fluid intelligence decline; crystallized intelligence (including semantic memory, or general knowledge base) is largely sustained. (594)

FUSE/GETTY IMAGES

- Retrieving words from long-term memory and planning what to say and how to say it in everyday conversation become more difficult; language comprehension and narrative competence are largely sustained. (598, 599)

FOGSTOCK/ALAMY

Note: Numbers in parentheses indicate the page or pages on which each milestone is discussed.

- Hypothetical problem solving declines, but everyday problem solving remains adaptive. (599)
- May hold an important position of leadership in society, such as chief executive officer, religious leader, or court justice. (600)

ROBERT NICHOLAS/GETTY IMAGES

- May develop wisdom. (600–601)
- Can improve a wide range of cognitive skills through training. (602)

### Emotional/Social

- Comes to terms with life, developing ego integrity. (610–611)
- Cognitive-affective complexity declines as basic information-processing skills diminish. (611)
- Displays positivity effect, selectively attending to and better recalling emotionally positive over negative information. (611)
- May engage in life-review reminiscence, but continues to seek avenues for personal growth and fulfillment. (612)

YADID LEVY/ALAMY

- Self-concept strengthens, becoming more secure and multifaceted. (612)
- Agreeableness and acceptance of change increase, while extroversion and openness to experience tend to decline. (614)

- Spirituality and faith may advance to a higher level, away from prescribed beliefs toward a more reflective approach. (614–615)

FUSE/GETTY IMAGES

- Size of social network declines, emphasizing emotionally positive, close relationships. (620–621)
- May be widowed. (628)
- Visits and support from siblings living nearby may increase. (630)
- With additional time to devote to them, friendships take on increasing importance. (630)
- May retire. (634–635)
- Likely to increase involvement in leisure and volunteer activities. (636)
- More likely to be knowledgeable about politics and to vote. (637)

## 80 YEARS AND OLDER

### Physical

- Physical changes previously listed continue.

MASKOT/GETTY IMAGES

- Mobility diminishes as muscle and bone strength and joint flexibility decline. (578)

### Cognitive

- Cognitive changes previously listed continue.
- Fluid intelligence declines further; crystallized intelligence drops as well, though only modestly. (594–595)

ROBERT HARDING

### Emotional/Social

- Emotional and social changes previously listed continue. (614)
- May develop gerotranscendence, a cosmic perspective directed beyond the self. (611)

HUGHEN LU/GETTY IMAGES

- Relationships with adult children become more important. (632)
- Frequency and variety of leisure and volunteer activities may decline. (636)

PETE LEONARD

Note: Numbers in parentheses indicate the page or pages on which each milestone is discussed.

## Death Education

As every life is unique, so each death is unique. The final forces of the human spirit separate themselves from the body in manifold ways.

My mother Sofie's death was the culmination of a five-year battle against cancer. In her last months, the disease invaded organs throughout her body, attacking the lungs in its final fury. She withered slowly, with the mixed blessing of time to prepare against certain knowledge that death was just around the corner. My father, Philip, lived another 18 years. At age 80, he was outwardly healthy, active, and about to depart on a long-awaited vacation when a heart attack snuffed out his life suddenly, without time for last words or deathbed reconciliations.

As I set to work on this chapter, my 65-year-old neighbor Nicholas gambled for a higher quality of life. To be eligible for a kidney transplant, he elected bypass surgery to strengthen his heart. Doctors warned that his body might not withstand the operation. But Nicholas knew that without taking a chance,

© CHARLES MISTRAL/ALAMY

he would live only a few years, in debilitated condition. Shortly after the surgery, infection set in, traveling throughout his system and so weakening him that only extreme measures—a respirator to sustain breathing and powerful drugs to elevate his fading blood pressure—could keep him alive.

“Come on, Dad, you can do it,” encouraged Nicholas's daughter Sasha, standing by his bedside and stroking his hand. But Nicholas could not. After two months in intensive care, he experienced brain seizures and slipped into a coma. Three doctors met with his wife, Giselle, to tell her there was no hope. She asked them to disconnect the respirator, and within half an hour Nicholas drifted away.

Death is essential for the survival of our species. We die so that our own children and the children of others may live. When it comes to this fate, nature treats humankind, with all its unique capabilities, just as it treats every other living creature. As hard as it is to accept the reality that we too will die, our greatest solace lies in knowing that death is part of ongoing life.

In this chapter, we address the culmination of lifespan development. Medical advances during the twentieth and early twenty-first centuries have provided so many means to keep death at bay that many people regard it as a forbidden topic. But pressing social and economic dilemmas that are an outgrowth of the dramatic increase in life expectancy are forcing us to attend to life's end—its quality, its timing, and ways to help people adjust to their own and others' final leave taking. The interdisciplinary field of **thanatology**, devoted to the study of death and dying, has expanded tremendously over the past three decades.

Our discussion addresses the physical changes of dying; understanding of and attitudes toward death in childhood, adolescence, and adulthood; the thoughts and feelings of people as they stand face to face with death; where people die; hopelessly ill patients' right to die; coping with the death of a loved one; and death education. The experiences of Sofie, Philip, Nicholas, their families, and others illustrate how each person's life history joins with social and cultural contexts to shape death and dying, lending great diversity to this universal experience. ●

## How We Die

**19.1** Describe the physical changes of dying, along with their implications for defining death and the meaning of death with dignity.

In industrialized countries, opportunities to witness the physical aspects of death are less available today than in previous generations. Most people in the developed world die in hospitals, where doctors and nurses, not loved ones, typically attend their last moments. Nevertheless, many want to know how we die, either to anticipate their own end or grasp what is happening to a dying loved one. As we look briefly at physical dying, we must keep in mind that the dying person is more than a physical being requiring care of and attention to bodily functions. The dying are also mind and spirit—for whom the end of life is still life. They benefit profoundly in their last days and hours from social support responsive to their needs for emotional and spiritual closure.

### Physical Changes

My father's fatal heart attack came suddenly during the night. When I heard the news, I longed for reassurance that his death had been swift and without suffering.

When asked how they would like to die, most people say they want “death with dignity”—either a quick, agony-free end during sleep or a clear-minded final few moments in which they can say farewell and review their lives. In reality, death is the culmination of a straightforward biological process. For about 20 percent of people, it is gentle—especially when narcotic drugs ease pain and mask the destructive events taking place (Nuland, 1993). But most of the time it is not.

Recall that unintentional injuries are the leading cause of death in childhood and adolescence, cardiovascular disease and cancer in adulthood. Of the one-quarter of deaths in industrialized nations that are sudden, 65 to 85 percent are due to heart attacks (Mozaffarian et al., 2015; Sanchis-Gomar et al., 2016). My yearning for a painless death for my father was probably not fulfilled. Undoubtedly he felt the sharp, crushing sensation of a heart deprived of oxygen. As his heart twitched uncontrollably (called *fibrillation*) or stopped entirely, blood circulation slowed and ceased, and he was thrust into unconsciousness. A brain

starved of oxygen for more than 2 to 4 minutes is irreversibly damaged—an outcome indicated by the pupils of the eyes becoming unresponsive to light and widening into large, black circles. Other oxygen-deprived organs stop functioning as well.

Death is long and drawn out for three-fourths of people—many more than in times past, as a result of life-saving medical technology. They succumb in different ways. Of those with heart disease, most have congestive heart failure, the cause of Nicholas's death (Murray & McLoughlin, 2012). His scarred heart could no longer contract with the force needed to deliver enough oxygen to his tissues. As it tried harder, its muscle weakened further. Without sufficient blood pressure, fluid backed up in Nicholas's lungs. This hampered his breathing and created ideal conditions for inhaled bacteria to multiply, enter the bloodstream, and run rampant in his system, leading many organs to fail.

Cancer also chooses diverse paths to inflict its damage. When it metastasizes, bits of tumor travel through the bloodstream and implant and grow in vital organs, disrupting their functioning. Medication made my mother's final days as comfortable as possible, granting a relatively easy death. But the preceding weeks involved physical suffering, including impaired breathing and digestion and turning and twisting to find a comfortable position in bed.

In the days or hours before death, activity declines; the person moves and communicates less and shows little interest in food, water, and surroundings. At the same time, body temperature, blood pressure, and circulation to the limbs fall, so the hands and feet feel cool and skin color changes to a duller, grayish hue (Hospice Foundation of America, 2011). When the transition from life to death is imminent, the person often moves through three phases:

- 1. The agonal phase.** The Greek word *agon* means “struggle.” Here agonal refers to a rattled breathing sound, due to fluid buildup in the throat, and to gasps and muscle spasms during the first moments in which the regular heartbeat disintegrates (Manole & Hickey, 2006).
- 2. Clinical death.** A short interval follows in which heartbeat, circulation, breathing, and brain functioning stop, but resuscitation is still possible.
- 3. Mortality.** The individual passes into permanent death. Within a few hours, the newly lifeless being appears shrunken, not at all like the person he or she was when alive.

### Defining Death

Consider what we have said so far, and note the dilemma of identifying just when death occurs. Death is not an event that happens at a single point in time but, rather, a process in which organs stop functioning in a sequence that varies from person to person. Because the dividing line between life and death is fuzzy, societies need a definition of death to help doctors decide when life-saving measures should be terminated, to signal survivors that they must begin to grieve their loss and reorganize their lives, and to establish when donated organs can be removed.

KARL JOHAENTGES/LOOK-FOTO/GETTY IMAGES

In a Chinese cemetery, family members pray and bring offerings to their deceased ancestors as a sign of respect. Buddhist, Confucian, and Shinto beliefs, which emphasize ancestor worship and time for the spirit to leave the corpse, may partly explain why brain death is not legally recognized in China.

Several decades ago, loss of heartbeat and respiration signified death. But these criteria are no longer adequate because resuscitation techniques frequently permit vital signs to be restored. Today, **brain death**, irreversible cessation of all activity in the brain and the brain stem (which controls reflexes), is used in most industrialized nations.

But not all countries accept this standard. In China and Japan, for example, doctors rely on traditional criteria—absence of heartbeat and respiration. This approach has hindered the development of national organ transplant programs because few organs can be salvaged from bodies without artificially maintaining vital signs. Buddhist, Confucian, and Shinto beliefs about death, which stress ancestor worship and time for the spirit to leave the corpse, may be partly responsible for this discomfort with brain death and organ donation (Yang & Miller, 2015). Today, Japanese law uses the brain death standard only when the dying person is a potential organ donor (Kumaido, Sugiyama, & Tsutsumi, 2015). Otherwise, people are considered to be alive until the heart stops beating. Brain death is still not legally recognized in China.

The brain death standard, however, does not always solve the problem of when to halt treatment. Consider Nicholas, who, though not brain dead, had entered a **persistent vegetative state**, in which the cerebral cortex no longer registered electrical activity but the brain stem remained active. Doctors were certain they could not restore consciousness or body movement. Because thousands of people in the United States and other nations are in a persistent vegetative state, with health-care costs totaling many millions of dollars annually, some experts believe that absence of activity in the cerebral cortex should be sufficient to declare a person dead. But others point to a few cases in which patients who had been vegetative for months regained cortical respon-

siveness and consciousness, though usually with very limited functioning (Laureys & Boly, 2007). In still other instances of illness, a fully conscious but suffering person refuses life-saving measures—an issue we will consider later when we take up the right to die.

## Death with Dignity

We have seen that nature rarely delivers the idealized, easy end most people want, nor can medical science guarantee it. Therefore, the greatest dignity in death is in the integrity of the life that precedes it—an integrity we can foster by the way we communicate with and care for the dying person.

First, we can assure the majority of dying people, who succumb gradually, that we will support them through their physical and psychological distress. We can treat them with respect by taking interest in those aspects of their lives that they most value and by addressing their greatest concerns (Keegan & Drick, 2011). And we can do everything possible to ensure the utmost compassionate care through their last months, weeks, and even final hours—restful physical surroundings, soothing emotional and social support, closeness of loved ones, and pastoral care that helps relieve worries about the worth of one's life, important relationships, and mortality.

Second, we can be candid about death's certainty. Unless people are aware that they are dying and understand (as far as possible) the likely circumstances of their death, they cannot plan for end-of-life care and decision making and share the sentiments that bring closure to relationships they hold most dear. Because Sofie knew how and when her death would probably take place, she chose a time when she and Philip could express what their lives had meant to each other. Among those precious bedside exchanges was Sofie's last wish that Philip remarry after her death so he would not live out his final years alone. Openness about impending death granted Sofie a final generative act,

Dying patient Dick Warner's wife, Nancy, wears a nurse's hat she crafted from paper to symbolize her dual roles as medical and emotional caregiver. The evening of this photo, Nancy heard Dick's breaths shortening. She kissed him and whispered, "It's time to let go." Dick died as he wished, with his loving wife at his bedside.

helped her let go of the person closest to her, and offered comfort as she faced death.

Finally, doctors and nurses can help dying people learn enough about their condition to make reasoned choices about whether to fight on or say no to further treatment. An understanding of how the normal body works simplifies comprehension of how disease affects it—education that can begin as early as the childhood years.

In sum, when the conditions of illness do not permit an easy death, we can still ensure the most dignified exit possible by offering the dying person care, affection, companionship, and esteem; the truth about diagnosis; and the maximum personal control over this final phase of life (American Hospice Foundation, 2013). These are essential ingredients of a “good death,” and we will revisit them throughout this chapter.

## Understanding of and Attitudes Toward Death

**19.2** Discuss age-related changes in conceptions of and attitudes toward death, and cite factors that influence death anxiety.

A century ago, when most deaths occurred at home, people of all ages, including children, helped with care of the dying family member and were present at the moment of death. They saw their loved one buried on family property or in the local cemetery, where the grave could be visited regularly. Because infant and childhood mortality rates were high, all people were likely to know someone their own age, or even younger, who had died. And it was common for children to experience the death of a parent.

Compared with earlier generations, today more young people reach adulthood without having experienced the death of someone they know well (Morgan, Laungani, & Palmer, 2009). When a death does occur, professionals in hospitals and funeral homes take care of most tasks that involve confronting it directly.

This distance from death undoubtedly contributes to a sense of uneasiness about it. Despite frequent images of death in television shows, movies, and news reports of accidents, murders, wars, and natural disasters, Americans live in a death-avoidant culture. Adults are often reluctant to talk about death with children and adolescents. And substitute expressions, such as “passing away,” “going out,” or “departing,” permit us to evade candid acknowledgment of death. In the following sections, we examine the development of conceptions of and attitudes toward death, along with ways to foster increased understanding and acceptance.

### Childhood

Four-year-old Miriam arrived at preschool the day after her dog Pepper died. Instead of joining the other children, she stayed

close to her teacher, Leslie, who noticed Miriam’s discomfort. “What’s wrong?” Leslie asked.

“Daddy said Pepper was so sick the vet had to put him to sleep.” For a moment, Miriam looked hopeful. “When I get home, Pepper might wake up.”

Leslie answered directly, “No, Pepper won’t get up again. He’s not asleep. He’s dead, and that means he can’t sleep, eat, run, or play anymore.”

Miriam wandered off but later returned to Leslie and, sobbing, confessed, “I chased Pepper too hard.”

Leslie put her arm around Miriam. “Pepper didn’t die because you chased him,” she explained. “He was very old and sick.”

Over the next few days, Miriam asked many questions: “When I go to sleep, will I die?” “Can a tummy ache make you die?” “Does Pepper feel better now?” “Will Mommy and Daddy die?”

**Development of the Death Concept.** An accurate, biological understanding of death is based on five subconcepts:

1. *Nonfunctionality.* All living functions, including thought, feeling, movement, and bodily processes, cease at death.
2. *Finality.* Once a living thing dies, it cannot be brought back to life.
3. *Universality.* All living things eventually die.
4. *Applicability.* Death applies only to living things.
5. *Causation.* Death is caused by a breakdown of bodily functioning, which can be brought about by a wide variety of internal and external causes.

To master these subconcepts, children must acquire some basic notions of biology—that animals and plants contain body parts (brain, heart, stomach; leaf, stem, roots) essential for maintaining life. They must also break down their global category of *not alive* into *dead*, *inanimate*, *unreal*, and *nonexistent*. Until children grasp these ideas, they tend to interpret death in terms of familiar experiences—as a change in behavior (Slaughter, Jaakkola, & Carey, 1999; Slaughter & Lyons, 2003). As a result, they are vulnerable to inaccurate beliefs—for example, that they caused a relative’s or pet’s death or that death is like sleep.

Children actively seek to make sense of death, and from age 3½ on, they make dramatic progress in acquiring its subconcepts, with most attaining a sophisticated understanding by age 6. Young children’s acquisition of biological knowledge about death is associated with reduced anxiety about death (Slaughter & Griffiths, 2007). These findings support discussing death truthfully with children, as Leslie did with Miriam.

*Nonfunctionality* (especially of bodily processes) and *finality* are generally understood early, even among children with little exposure to the death of relatives or pets, perhaps because preschoolers see evidence for these subconcepts in everyday situations—for example, in the dead butterflies and beetles they pick up and inspect while playing outside. Appreciation of *universality* soon follows. At first, many preschoolers think that

Children light candles in remembrance of a deceased family member during the annual *Día de los Muertos* (“Day of the Dead”) celebration. Because their parents value forthright discussions, Mexican-American children freely ask questions about the biology of death and death-related cultural traditions.

certain people will not die—themselves, people like themselves (other children), and people with whom they have close emotional ties. *Applicability* and *causation* are more challenging (Kenyon, 2001; Panagiotaki et al., 2015; Rosengren, Gutiérrez, & Schein, 2014). As preschoolers refine the distinction between animate and inanimate, they realize that dolls, robots, and other lifelike inanimate objects cannot die. And by age 6, their grasp of internal (illness, old age) and external (accidents) causes of death is substantial (Lazar & Torney-Purta, 1991).

Regardless of religious background, nearly 65 percent of U.S. adults believe in some kind of persistence of a spirit or soul after death (Harris Poll, 2013). When researchers asked American preschoolers whether some aspect remains after living beings die, most gave biological answers, mentioning the body, body parts, or bones. But some spoke of a spirit that “goes to heaven” (Nguyen & Rosengren, 2004; Rosengren, Gutiérrez, & Schein, 2014). These afterlife beliefs strengthen over early and middle childhood, with the majority of 10- to 12-year-olds expressing belief in the survival of a soul that enables the dead to perceive, think, and feel (Bering & Bjorklund, 2004; Harris & Giménez, 2005). Because many adults also believe in the persistence of mental activity and consciousness after death, they probably encourage these ideas in children (Harris, 2011). It is not surprising, then, that most older children conclude that even after biological functions cease at death, thoughts and feelings continue in some form.

**Cultural and Individual Variations.** Although children typically attain an adultlike, biological understanding of death by the end of early childhood, individual differences exist. Cultural and religious ideas influence children’s rate of mastery and how they acquire information.

Interviews with European-American parents of preschoolers revealed that parent’s talk about death is often indirect and avoidant. For example, when one child asked where his dead pet mouse had gone, his mother responded, “Someplace happy” (Miller et al., 2014). The majority of parents also said they shielded their children from movies and TV programs depicting death. They defended their protective stance by arguing that young children lack the cognitive and emotional capacities to understand and cope with death—opinions at odds with research evidence. The children nevertheless picked up information through conversations with siblings and peers and overheard fragments of radio and TV broadcasts. Their parents were unable to shield them completely.

In contrast, responses of Mexican-American immigrant parents emphasized the importance of informative, forthright discussions about death from an early age and access to media depictions (except where content is violent). Death, they explained, is natural and inevitable, and opportunities to recall deceased loved ones and be reminded of an emotional and spiritual connection to them are comforting. In keeping with Mexican cultural traditions, most parents reported participating in the annual *Día de los Muertos* (“Day of the Dead”) celebration, during which many symbols of death are displayed. One tradition involves welcoming the spirits of departed relatives by making an altar, which contains photos, food offerings, decorations, and images of skulls and skeletons (Gutiérrez, Rosengren, & Miller, 2014). Compared to their European-American counterparts, the Mexican-American parents reported that their preschoolers asked many more questions about death, mostly pertaining to biological subconcepts and cultural traditions.

Other research highlights ways that religious teachings affect children’s understanding. In a comparison of four ethnic groups in Israel, Druze and Muslim children’s ideas about death differed from those of Christian and Jewish children (Florian & Kravetz, 1985). The Druze emphasis on reincarnation, and the greater religiosity of both Druze and Muslim groups, likely led more of their children to deny that death is final and that the body ceases to function.

Terminally ill children under age 6 usually have a well-developed biological understanding of death (Linebarger, Sahler, & Egan, 2009; Nielson, 2012). If parents and health professionals have not been forthright, the children discover they are deathly ill in other ways—through nonverbal communication, eavesdropping, talking with other child patients, and perceiving physiological changes in their bodies. Children growing up on Israeli kibbutzim (agricultural settlements) who have witnessed terrorist attacks, family members’ departure on army tours, and parental anxiety about safety express a mature grasp of death by age 5 (Mahon, Goldberg, & Washington, 1999).

**Enhancing Children’s Understanding.** We have seen that children with a good grasp of the facts of death express less anxiety about it. Direct explanations, like Leslie’s, that fit the child’s capacity to understand work best. Sometimes children ask difficult questions, such as “Will I die?” “Will you die?” Parents

can be truthful as well as comforting by taking advantage of the child's sense of time: "Someday I will die, but I hope not for many, many years. First I want to enjoy you as a grownup and be a grandparent."

Another way to foster an accurate appreciation of death is to teach young children about human biology. Three- to 5-year-olds given lessons in the role of the heart, brain, lungs, stomach, and other organs in sustaining life have more advanced death concepts than children not given such lessons (Slaughter & Lyons, 2003).

Adult-child discussions should also be culturally sensitive. Rather than presenting scientific evidence as negating religious beliefs, parents and teachers can help children blend the two sources of knowledge. As noted earlier, preschool and school-age children often combine their biological appreciation of death with religious and spiritual views, which offer solace in times of bereavement (Talwar, 2011). As we will see later, open, honest discussions not only contribute to a realistic understanding of death but also facilitate grieving after a child has experienced a loss.

## Adolescence

Teenagers can easily explain death subconcepts of nonfunctionality and finality, but they are attracted to alternatives. For example, adolescents often describe death as an enduring abstract state—"darkness," "eternal light," "transition," or "nothingness" (Brent et al., 1996). They also formulate personal theories about life after death. Besides images of heaven and hell influenced by their religious background, they speculate about reincarnation, transmigration of souls, and spiritual survival on earth or at another level (Noppe & Noppe, 1997; Yang & Chen, 2002).

Although mortality in adolescence is low compared with that in infancy and adulthood, teenage deaths are typically

sudden and human-induced; unintentional injuries, homicide, and suicide are leading causes. Adolescents are clearly aware that death happens to everyone and can occur at any time. But as their high-risk activities suggest, they do not take death personally.

What explains teenagers' difficulty integrating logic with reality in the domain of death? First, adolescence is a period of rapid growth and onset of reproductive capacity—attainments that are the opposite of death! Second, recall that in adolescent brain development, the prefrontal cognitive control network is not yet able to manage the stress reactivity and sensation-seeking impulses emanating from the brain's emotional/social network—an imbalance that contributes to teenagers' tendency to take unnecessary chances with their lives. When they drive recklessly or play "chicken" with a speeding train and survive, they may experience the illusion of control over death, which prompts them to take additional death-defying risks. Finally, the adolescent personal fable—teenagers' conviction that they are special and unique—may also convince them that they are beyond reach of death.

By encouraging adolescents to discuss concerns about death, adults can help them build a bridge between death as a logical possibility and their everyday actions. Taking up adolescents' thoughts and feelings can be part of everyday conversation, sparked by a news report or the death of an acquaintance. Parents can capitalize on these moments to express their own views, listen closely, accept teenagers' feelings, and correct misconceptions. Such mutual sharing deepens bonds of love and provides the basis for further exploration when the need arises. Applying What We Know on the following page suggests ways to discuss concerns about death with children and adolescents.

## Adulthood

In early adulthood, many people brush aside thoughts of death (Corr & Corr, 2013). This avoidance may be prompted by death anxiety, which we will consider in the next section. Alternatively, it may be due to relative lack of interest in death-related issues, given that young adults typically do not know very many people who have died and (like adolescents) think of their own death as a long way off.

In Chapters 15 and 16, we described midlife as a time of stock taking in which people begin to view the lifespan in terms of time left to live and focus on tasks to be completed. Middle-aged people no longer have a vague conception of their own death. They know that in the not-too-distant future, it will be their turn to grow old and die.

In late adulthood, adults think and talk more about death because it is much closer. Increasing evidence of mortality comes from physical changes, higher rates of illness and disability, and loss of relatives and friends (see Chapter 17). Compared with middle-aged people, older adults spend more time pondering the process and circumstances of dying than the state of death (Kastenbaum, 2012). Nearness to death seems to lead to a practical concern with how and when it might happen.

These British youths carry the coffin of a 16-year-old who was stabbed to death during a gang attack. Although teenagers grasp death's finality and nonfunctionality, they may speculate about alternative possibilities for life after death.

## Applying what we Know

### Discussing Concerns About Death with Children and Adolescents

SUGGESTION	DESCRIPTION
Take the lead.	Be alert to the child's or adolescent's nonverbal behaviors, bringing up the subject sympathetically, especially after a death-related situation has occurred.
Listen perceptively.	Give full attention to the child or adolescent and the feelings underlying his or her words. When adults pretend to listen while thinking about other things, young people quickly pick up this sign of indifference and withdraw their confidence.
Acknowledge feelings.	Accept the child's or adolescent's emotions as real and important; avoid being judgmental. For example, paraphrase sentiments you detect, such as "I see you're very puzzled about that. Let's talk more about it."
Provide factual information in a candid, culturally sensitive fashion.	For children who do not yet have a realistic understanding of death, provide simple, direct, and accurate explanations. Avoid misleading statements, such as "went for a rest" or "sleeping." Do not contradict the young person's religious beliefs. Rather, assist him or her in blending biological with religious knowledge.
Engage in joint problem solving.	When questions do not have easy answers, such as "Where does your soul go when you die?," convey your belief in the young person's worth by indicating that you do not want to impose a point of view but rather to help him or her come to personally satisfying conclusions. To questions you cannot answer, say, "I don't know." Such honesty shows a willingness to generate and evaluate solutions jointly.

Finally, although we have traced overall age-related changes, large individual differences exist. Some adults focus on life and death issues early on; others are less reflective, moving into old age without giving these matters much attention.

## Death Anxiety

As you read the following statements, do you find yourself agreeing, disagreeing, or reacting neutrally?

"Never feeling anything again after I die upsets me."

"I hate the idea that I will be helpless after I die."

"The total isolation of death is frightening to me."

"The feeling that I will be missing out on so much after I die disturbs me." (Thorson & Powell, 1994, pp. 38–39)

Items like these appear on questionnaires used to measure **death anxiety**—fear and apprehension of death. Even people who clearly accept the reality of death may fear it.

What predicts whether thoughts of our own demise trigger intense distress, relative calm, or something in between? To answer this question, researchers measure both general death anxiety and specific factors—fear of no longer existing, loss of control, a painful death, decay of the body, separation from loved ones, and the unknown (Neimeyer, 1994). Findings reveal large individual and cultural variations in aspects of death that arouse fear. For example, in a study of devout Islamic Saudi Arabians, certain factors that appear repeatedly in the responses of Westerners, such as fear of the body decaying and of the unknown, were entirely absent (Long, 1985).

Among Westerners, spirituality—a sense of life's meaning—seems more important than religious commitment in limiting death anxiety (Ardelt, 2003; Routledge & Juhl, 2010). And in two studies, Christian older adults whose religious beliefs and behavior were contradictory—who believed in a rewarding afterlife but rarely prayed or attended services, or who regularly prayed and attended services but doubted the existence of an afterlife—reported higher death anxiety (Wink, 2006; Wink & Scott, 2005). Together, these findings indicate that both firmness of beliefs and consistency between beliefs and practices, rather than religiousness itself, reduce fear of death. Death anxiety is especially low among adults with deep faith in some form of higher force or being—faith that may or may not be influenced by religion (Cicirelli, 2002; Neimeyer et al., 2011).

People with a well-developed, positive personal philosophy of death are also less fearful. In one study, researchers distinguished between two philosophies: a *participatory perspective*, in which death and dying are viewed as natural and life-promoting, as fulfillment of life goals, and as a time to share one's experiences with others; and an *overcoming perspective*, in which death is seen as imposed on people, as defeat or failure, and as robbing them of opportunities to achieve their goals (Petty et al., 2015). Among adults ranging in age from 18 to 83, "participators" were less fearful of death than "overcomers."

From what you have learned about adult psychosocial development, how do you think death anxiety might change with age? If you predicted it would decline, reaching its lowest level in late adulthood, you are correct (see Figure 19.1 on page 652) (Russac et al., 2007; Tomer, Eliason, & Smith, 2000). This age-related drop has been found in many cultures and ethnic groups.

**FIGURE 19.1** Relationship of age and gender to death anxiety.

In this study comparing young and older adults, death anxiety declined with age. Women expressed greater fear of death than men. Many other studies show similar findings. (Based on Tomer, Eliason, & Smith, 2000.)

Recall from Chapter 18 that older adults are especially effective at regulating negative emotion. As a result, most cope with anxieties, including fear of death, effectively. Furthermore, attainment of ego integrity reduces death anxiety. Older people have had more time to develop symbolic immortality—the belief that one will continue to live on through one’s children or through one’s work or personal influence (see Chapter 16, page 539).

As long as it is not overly intense, death anxiety can motivate people to strive to live up to internalized cultural values—for example, to be kind to others and to work hard to reach one’s goals. These efforts increase adults’ sense of self-esteem, self-efficacy, and purpose in life—powerful antidotes against the terrifying thought that, in the overall scheme of things, they “are no more important or enduring than any individual potato, pineapple, or porcupine” (Fry, 2003; Pyszczynski et al., 2004, p. 436). In a study of Israeli adults, symbolic immortality predicted reduced fear of death, especially among those with secure attachments (Florian & Mikulincer, 1998). Gratifying, close interpersonal ties seem to help people feel worthwhile and forge a sense of symbolic immortality. And people who view death as an opportunity to pass a legacy to future generations are less likely to fear it (Cicirelli, 2001; Mikulincer, Florian, & Hirschberger, 2003).

Regardless of age, in both Eastern and Western cultures, women appear more anxious about death than men do (refer again to Figure 19.1) (Madnawat & Kachhawa, 2007; Tomer, Eliason, & Smith, 2000). Women may be more likely to admit and men more likely to avoid troubled feelings about mortality—an explanation consistent with females’ greater emotional expressiveness throughout the lifespan. Furthermore, in one study, women showed a temporary rise in death anxiety in their early fifties not seen in men (Russac et al., 2007). Perhaps menopause, in marking the end of reproductive capacity, provides women with a stark reminder of their mortality.

Experiencing some anxiety about death is normal and adaptive. But like other fears, very intense death anxiety can undermine effective adjustment. Although physical health in adulthood is not related to death anxiety, mental health clearly is. In cultures as different as China and the United States, people who are depressed or generally anxious tend to have more severe death concerns (Neimeyer & Van Brunt, 1995; Wu, Tang, & Kwok, 2002). In contrast, people who are good at inhibition (keeping their minds from straying to irrelevant thoughts) and at emotional self-regulation report less death anxiety (Bodner et al., 2015; Gailliot, Schmeichel, & Baumeister, 2006). They are better able to manage their concerns about death.

Death anxiety is largely limited to adolescence and adulthood. Children rarely display it unless they live in high-crime neighborhoods or war-torn areas where they are in constant danger (see the Cultural Influences box on the impact of ethnic and political violence on children on page 359 in Chapter 10). Terminally ill children are also at risk for high death anxiety. Compared with other same-age patients, children with cancer express more destructive thoughts and negative feelings about death (Malone, 1982). For those whose parents make the mistake of not telling them they are going to die, loneliness and death anxiety can be extreme (O’Halloran & Altmaier, 1996).

MICHEL PORRO/GETTY IMAGES

Death anxiety declines in old age, and this 81-year-old from the Netherlands seems to have very little! She had this coffin made to serve as a bookshelf because, she said, “It’s a waste to use a coffin just for burial.” The pillow on the top will support her head after she dies.

## Ask yourself

**CONNECT** How do advances in cognition contribute to adolescents' understanding of death? (Refer to Chapter 11, pages 388–389 and 392–393.)

**APPLY** When 4-year-old Chloe's aunt died, Chloe asked, "Where's Aunt Susie?" Her mother explained, "Aunt Susie is taking a long, peaceful sleep." For the next two weeks, Chloe refused to go to bed, and, when finally coaxed into her room, lay awake for hours. What is the likely reason for Chloe's behavior? What might be a better way of answering her question?

**REFLECT** Ask members of earlier generations in your family about their childhood experiences with death. Compare these to your own experiences. What differences did you find, and how would you explain them?

## Thinking and Emotions of Dying People

**19.3** Describe and evaluate Kübler-Ross's theory of typical responses to dying, and cite factors that influence dying patients' responses.

In the year before her death, Sofie did everything possible to surmount her illness. In between treatments to control the cancer, she tested her strength. She continued to teach high school, traveled to visit her children, cultivated a garden, and took weekend excursions with Philip. Hope pervaded Sofie's approach to her deadly condition, and she spoke often about the disease—so much so that her friends wondered how she could confront it so directly.

As Sofie deteriorated physically, she moved in and out of various mental and emotional states. She was frustrated, and at times angry and depressed, about her inability to keep on fighting. I recall her lamenting anxiously on a day when she was in pain, "I'm sick, so very sick! I'm trying so hard, but I can't keep on." Once she asked when my husband and I, who were newly married, would have children. "If only I could live long enough to hold them in my arms!" she cried. In the last week, she appeared tired but free of struggle. Occasionally, she spoke of her love for us and commented on the beauty of the hills outside her window. But mostly, she looked and listened, rather than actively participating in conversation. One afternoon, she fell permanently unconscious.

### Do Stages of Dying Exist?

As dying people move closer to death, do they go through a series of changes that are the same for everyone, or are their thoughts and feelings unique?

**Kübler-Ross's Theory.** Although her theory has been heavily criticized, Elisabeth Kübler-Ross (1969) is credited with awakening society's sensitivity to the psychological needs of dying

patients. From interviews with over 200 terminally ill people, she devised a theory of five typical responses—initially proposed as stages—to the prospect of death and the ordeal of dying: (1) *denial*—refusing to accept the diagnosis and avoiding discussions with doctors and family members, as a means of escaping from the prospect of death; (2) *anger*—resentment and fury that time is short, that goals may be left unattained, and at the unfairness of death; (3) *bargaining*—striking bargains with doctors, nurses, family members, friends, or God for extra time; (4) *depression*—with realization of the inevitability of death, despondency about the impending loss of one's life; and (5) *acceptance*—the weakened patient reaches a state of peace, usually in the last few days, and disengages from all but a few family members, friends, and caregivers.

Although Kübler-Ross cautioned that her five stages should not be viewed as a fixed sequence and that not all people display each response, her choice of the term *stages* has made it easy for her theory to be interpreted simplistically, as steps a "normal" dying person follows. Decades of research have yielded no evidence for a universal, linear sequence of stages experienced by dying people (Corr, 2015b). Yet some health professionals, unaware of diversity in dying experiences, have insensitively tried to push patients through Kübler-Ross's stages. And caregivers, through callousness or ignorance, can too easily dismiss a dying patient's legitimate complaints about treatment as "just what you would expect in Stage 2" (Corr & Corr, 2013; Kastenbaum, 2012).

Rather than stages, the five reactions Kübler-Ross observed are best viewed as coping strategies that anyone may call on in the face of threat. Furthermore, dying people respond in many additional ways—for example, through efforts to conquer the disease, as Sofie displayed; through an overwhelming need to control what happens to their bodies during the dying process; through acts of generosity and caring; through shifting their focus to living in a fulfilling way—"seizing the day" because so little time is left; and through sadness, relief, isolation, hope, and other emotional reactions (Silverman, 2004; Wright, 2003).

Consider Tony, a 15-year-old leukemia patient, who said to his mother, "I don't want to die yet. Gerry [youngest brother] is only 3 and not old enough to understand. If I could live just one more year, I could explain it to him myself and he will understand" (Komp, 1996, pp. 69–70). Tony's adaptation stresses compassion and altruism; bargaining fails to capture it. Following a diagnosis of terminal lung cancer, my friend Paul devoted as much time as possible to drafting a new book. One way he coped with dying was to immerse himself in work he found intensely satisfying, nearly completing the project several weeks before he died. As these examples suggest, the most serious drawback to Kübler-Ross's theory is that it looks at dying patients' thoughts and feelings outside the contexts that give them meaning.

Kübler-Ross's legacy lies in convincing professionals and the general public that the dying are living people who usually have "unfinished needs" they want to address. As we will see next, people's adaptations to impending death can be understood only in relation to the multidimensional influences that have contributed to their life course and that also shape this final phase.

## Contextual Influences on Adaptations to Dying

From the moment of her diagnosis, Sofie spent no time denying the deadliness of her disease. Instead, she met it head on, just as she had dealt with other challenges of life. Her impassioned plea to hold her grandchildren in her arms was not a bargain with fate but rather an expression of profound defeat that on the threshold of late adulthood, she would not live to enjoy its rewards. At the end, her quiet, withdrawn demeanor was probably resignation, not acceptance. All her life, she had been a person with a fighting spirit, unwilling to give in to challenge.

According to recent theorists, a single strategy, such as acceptance, is not best for every dying patient. Rather, an **appropriate death** is one that makes sense in terms of the individual's pattern of living and values and, at the same time, preserves or restores significant relationships and is as free of suffering as possible (Worden, 2000). When asked about a "good death," most patients are clear about what, ideally, they would like to happen. They mention the following goals:

- Maintaining a sense of identity, or inner continuity with one's past
- Clarifying the meaning of one's life and death
- Maintaining and enhancing close relationships
- Achieving a sense of control over the time that remains
- Confronting and preparing for death (Goldstein et al., 2006; Kleespies, 2004; Proulx & Jacelon, 2004; Reinke et al., 2013)

© GALE GETTINGER

Dr. Paul Kalanithi, shown here with his wife, Lucy, and daughter, Cady, was diagnosed with incurable lung cancer at age 36. He continued to practice neurosurgery as long as possible, became a father, and authored the memoir *When Breath Becomes Air*, in which he urged others to make the most of their life and time. He died less than two years later, having approached his death in a way that suited his pattern of living and deepest values.

Research reveals that biological, psychological, and social and cultural forces affect people's coping with dying and, therefore, the extent to which they attain these goals. Let's look at some important influences on how people fare.

**Nature of the Disease.** The course of the illness and its symptoms affect the dying person's reactions. For example, the extended nature of Sofie's illness and her doctor's initial optimism about achieving a remission undoubtedly contributed to her attempts to try to conquer the disease. During the final month, when cancer had spread to Sofie's lungs and she could not catch her breath, she was agitated and fearful until oxygen and medication relieved her uncertainty about being able to breathe. In contrast, Nicholas's weakened heart and failing kidneys so depleted his strength that he responded only with passivity.

Because of the toll of the disease, about 25 percent of cancer patients show symptoms of severe depression—reactions distinct from the sadness, grief, and worry that typically accompany the dying process (Walker et al., 2014). Profound depression amplifies pain, impairs the immune response, interferes with the patient's capacity for pleasure, meaning, and connection, and is associated with poorer survival (Satin, Linden, & Phillips, 2009; Williams & Dale, 2006). It therefore requires immediate treatment. Among the most successful approaches are meaning-focused life review (see page 612 in Chapter 18), medical control of pain, and advance care planning with the patient that ensures that his or her end-of-life wishes are known and respected (Rosenstein, 2011).

**Personality and Coping Style.** Understanding the way individuals view stressful life events and have coped with them in the past helps us appreciate the way they manage the dying process. In a study in which terminally ill patients discussed their images of dying, responses varied greatly. For example,

- Beth regarded *dying as imprisonment*: "I felt like the clock started ticking ... like the future has suddenly been taken.... In a way, I feel like I'm already dead."
- To Faith, dying was *a mandate to live ever more fully*: "I have a saying: ... 'You're not ready to live until you're ready to die.' ... It never meant much to me until I ... looked death in the eye, and now I'm living.... This life is a lot better than the one before."
- Dawn viewed dying as *part of life's journey*: "I learned all about my disease.... I would read, read, read.... I wanted to know as much as I can about it, and I don't think hiding ... behind the door ... could help me at all. And, I realized for the first time in my life—*really, really, really realized* that I could handle anything."
- Patty approached dying as *an experience to be transformed* so as to make it more bearable: "I am an avid, rabid fan of *Star Trek*, a trekkie like there never has been.... I watch it to the point that I've memorized it.... [In my mind, I play the various characters so] I'm not [always] thinking about cancer or dying.... I think that's how I get through it." (Wright, 2003, pp. 442–444, 447)

Each patient's view of dying helps explain his or her responses to worsening illness. Poorly adjusted individuals—those with conflict-ridden relationships and many disappointments in life—are usually more distressed (Kastenbaum, 2012).

### Family Members' and Health Professionals' Behavior.

Earlier we noted that a candid approach, in which everyone close to and caring for the dying person acknowledges the terminal illness, is best. Yet this also introduces the burden of participating in the work of dying with the patient—bringing relationships to closure, reflecting on life, and dealing with fears and regrets.

People who find it hard to engage in these tasks may pretend that the disease is not as bad as it is. In patients inclined toward denial, a “game” can be set in motion in which participants are aware that the patient is dying but act as though it were not so. Though this game softens psychological pain for the moment, it makes dying much more difficult. Besides impeding communication, it frequently leads to futile medical interventions, in which the patient has little understanding of what is happening and is subjected to great physical and emotional suffering. One attending physician provided this account of a cancer patient's death:

The problem was that she had a young husband and parents who were pretty much in complete denial. We were trying to be aggressive up to the end. To the point that we actually hung a new form of chemotherapy about four hours before she died, even though everybody knew except her immediate family that she was going to die within the next four to eight hours. (Jackson et al., 2005, p. 653)

At other times, the patient suspects what he or she has not been told. In one instance, a terminally ill child flew into a rage because his doctor and a nurse spoke to him in ways that denied the fact that he would not grow up. Trying to get the child to cooperate with a medical procedure, the doctor said,

“I thought you would understand, Sandy. You told me once you wanted to be a doctor.”

He screamed back, “I'm not going to be anything!” and threw an empty syringe at her.

The nurse standing nearby asked, “What are you going to be?”

“A ghost,” said Sandy, and turned away from them. (Bluebond-Langner, 1977, p. 59)

The behavior of health professionals impeded Sandy's efforts to form a realistic time perspective and intensified his anger at the injustice of his premature death.

When doctors want to inform patients of their prognosis, they may encounter resistance from family members, especially in certain cultures. Withholding information is common in Southern and Eastern Europe, Central and South America, much of Asia, and the Middle East. In China, Korea, and Japan, terminally ill patients are often not told the truth, out of concern that telling might disrupt family relationships and harm patients' well-being (Mo et al., 2011; Seki et al., 2009). Although attitudes

A doctor listens sympathetically to the concerns of a terminally ill patient. Through sensitive, open communication, health professionals help dying people prepare for death by bringing relationships to closure, reflecting on life, and dealing with fears and regrets.

are changing among U.S. immigrant groups, a substantial minority of Korean Americans and Mexican Americans continue to believe that informing patients is wrong and that health-care decisions should instead be made by family members (Ko et al., 2014; Mead et al., 2013). In these instances, providing information is complex. When a family insists that a patient not be told, the doctor can first offer information to the patient and then, if the patient refuses, ask who should receive information and make health-care decisions. The patient's preference can be honored and reassessed at regular intervals.

Care of the terminally ill is demanding and stressful. Nurses who respond effectively to the psychological needs of dying patients and their families benefit from inservice training aimed at strengthening interpersonal skills, day-to-day mutual support among staff, and development of a personal philosophy of death (Efsthathiou & Clifford, 2011; Hebert, Moore, & Rooney, 2011; Morris, 2011). Extensive experience working with dying patients in a sensitive, supportive environment is associated with low death anxiety, perhaps because such caregivers observe their patients' distress decline and, thus, gradually learn that their own previous fears are less founded (Bluck et al., 2008; Peters et al., 2013).

Social support from family members also affects adaptation to dying. Dying patients who feel they have much unfinished business to attend to are more anxious about impending death. Family contact reduces their sense of urgency to prolong life, likely by permitting them to work through at least some incomplete tasks (Mutran et al., 1997; Zimmerman, 2012). Granting and seeking forgiveness for past hurts is a powerful means of relieving distress and inducing life closure among the terminally ill. Unresolved forgiveness issues, in contrast, are linked to greater anger and anxiety and reduced sense of life completion (Baker, 2005; Prince-Paul, Zyzanski, & Exline, 2013). When counselors help family members express end-of-life forgiveness, terminally ill patients gain in psychological well-being.

## Applying what we Know

### Communicating with Dying People

SUGGESTION	DESCRIPTION
Be truthful about the diagnosis and course of the disease.	Be honest about what the future is likely to hold, thereby permitting the dying person to bring closure to his or her life by expressing sentiments and wishes and participating in decisions about treatment.
Listen perceptively and acknowledge feelings.	Be truly present, focusing full attention on what the dying person has to say and accepting the patient's feelings. Patients who sense another's presence and concern are more likely to relax physically and emotionally and express themselves.
Maintain realistic hope.	Assist the dying person in maintaining hope by encouraging him or her to focus on a realistic goal that might yet be achieved—for example, resolution of a troubled relationship or special moments with a loved one. Knowing the dying person's hope, family members and health professionals can often help fulfill it.
Assist in the final transition.	Assure the dying person that he or she is not alone, offering a sympathetic touch, a caring thought, or just a calm presence. Some patients who struggle may benefit from being given permission to die—the message that giving up and letting go are all right.

Source: Lugton, 2002.

Effective communication with the dying person is honest, fostering a trusting relationship, yet also oriented toward maintaining hope. Many dying patients move through a hope trajectory—at first, hope for a cure; later, hope for prolonging life; and finally, hope for a peaceful death with as few burdens as possible (Fanslow, 1981). Once patients near death stop expressing hope, those close to them must accept this. Family members who find letting go very difficult may benefit from expert guidance. Applying What We Know above offers suggestions for communicating with the dying.

**Spirituality, Religion, and Culture.** Earlier we noted that a sense of spirituality reduces fear of death. Research indicates that this is as true for the dying as for people in general. Terminally ill patients who score higher in spiritual well-being (belief in life's meaning) express a greater sense of inner peace (feeling relaxed, positive, forgiving of themselves and others, and accepting of their life situation) and less end-of-life despair (desire for a hastened death and suicidal thoughts) (McClain, Rosenfeld, & Breitbart, 2003; McClain-Jacobson et al., 2004; Selman et al., 2013). As one experienced nurse commented,

At the end, those [patients] with a faith—it doesn't really matter in what, but a faith in something—find it easier. Not always, but as a rule. I've seen people with faith panic and I've seen those without faith accept it [death]. But, as a rule, it's much easier for those with faith. (Samarel, 1991, pp. 64–65)

Vastly different cultural beliefs, guided by religious ideas, also shape people's dying experiences:

- Buddhism, widely practiced in China, India, and Southeast Asia, emphasizes that all physical and mental states are transient, which fosters acceptance of death. By chanting sutras (teachings of Buddha) to the dying to calm the mind and

emphasizing that death leads to rebirth (moving through a variety of lives on a journey toward enlightenment), Buddhists believe that it is possible for the dying person to attain Nirvana, a transcendent state in which there is no suffering, desire, or sense of self (Goin, 2015; Kubotera, 2004).

- In many Native-American groups, death is met with stoic self-control, an approach taught at an early age through stories that emphasize a circular, rather than linear, relationship between life and death and the importance of making way for others (Sharp et al., 2015).
- For African Americans, a dying loved one signals a crisis that unites family members in caregiving (Jenkins et al., 2005). The terminally ill person remains an active and vital force within the family until he or she can no longer carry out this role—an attitude of respect that eases the dying process.
- Among the Maori of New Zealand, relatives and friends gather around the dying person to give spiritual strength and comfort. Older adults, clergy, and other experts in tribal customs conduct a *karakia* ceremony, in which they recite prayers asking for peace, mercy, and guidance from the creator. After the ceremony, the patient is encouraged to discuss important matters with closest loved ones—giving away of personal belongings, directions for interment, and completion of other unfinished tasks (Ngata, 2004; Oetzel et al., 2015).

In sum, dying prompts a multitude of thoughts, emotions, and coping strategies. Which ones are emphasized depends on a wide array of contextual influences. A vital assumption of the lifespan perspective—that development is multidimensional and multidirectional—is just as relevant to this final phase as to each earlier period.

## A Place to Die

**19.4** Evaluate the extent to which homes, hospitals, nursing homes, and the hospice approach meet the needs of dying people and their families.

Whereas in the past most deaths occurred at home, in the United States today about 40 percent take place in hospitals and another 20 percent in long-term care facilities, usually nursing homes. Nearly 30 percent of people age 65 and older experience a hospital intensive care unit (ICU) in the last month of life, most of whom die there (Centers for Disease Control and Prevention, 2016e; Teno et al., 2013). In the large, impersonal hospital environment, meeting the human needs of dying patients and their families is usually secondary, not because professionals lack concern, but because their work focuses on saving lives. A dying patient represents a failure.

In the 1960s, a death awareness movement arose as a reaction to hospitals' death-avoiding practices—attachment of complicated machinery to patients with no chance of survival and avoidance of communication with dying patients. This movement soon led to medical care better suited to the needs of dying people and also to hospice programs, which have spread to many countries in the industrialized world. Let's visit each of these settings for dying.

### Home

Had Sofie and Nicholas been asked where they wanted to die, undoubtedly each would have responded, "At home"—the preference of 80 percent of Americans (NHPCO, 2013). The reason is clear: The home can offer an atmosphere of intimacy and loving care in which the terminally ill person is unlikely to feel abandoned or humiliated by physical decline or dependence on others.

Although U.S. home deaths have increased over the past two decades, dying at home remains a distant reality for many: Only about one-fourth of Americans experience it, more often those who are financially better off (Centers for Disease Control and Prevention, 2016e). And it is important not to romanticize dying at home. Because of dramatic improvements in medicine, dying people tend to be sicker or much older than in the past. Consequently, their bodies may be extremely frail, making ordinary activities—eating, sleeping, taking a pill, toileting, and bathing—major ordeals for informal caregivers (Milligan et al., 2016). Health problems of aging spouses, work and other responsibilities of family members, and the physical, psychological, and financial strain of providing home care can make it difficult to honor a terminally ill person's wish to die at home.

For many family members, the chance to be with the dying person until the very end is a rewarding tradeoff for the high demands of caregiving. But to make dying at home feasible, adequate support for the caregiver is essential (Karlsson & Berggren, 2011). A specially trained home health aide is usually

necessary—a service (as we will see shortly) that hospice programs have made more accessible. Furthermore, even with professional help, most homes are poorly equipped to handle the medical and comfort-care needs of the dying. Hospital-based equipment and technical support often must be transported to the home.

Overall, the evidence is inconsistent on whether home deaths are associated with less pain and increased satisfaction for patients and reduced distress for family members than deaths occurring in hospitals (Higginson et al., 2013; Shepperd et al., 2016). Contributing to these mixed outcomes, a considerable number of aging adults, rather than dying in their own home, die in a family member's home—often an adult child's. Modifications to the physical structure and addition of equipment to accommodate the dying person's needs, along with the intensity of caregiving tasks, can disrupt caregivers' own sense of home, with negative consequences for psychological well-being (Milligan et al., 2016). And dying older adults' concerns about burdening their adult children, along with regret at having lost the identity, security, privacy, and personal control they had in their own home, can contribute to anxiety and dissatisfaction as well.

### Hospital

Hospital dying takes many forms. Each is affected by the physical state of the dying person, the hospital unit in which it takes place, and the goal and quality of care.

Sudden deaths, due to injury or critical illness, typically occur in emergency rooms. Doctors and nurses must evaluate the problem and take action quickly. Little time is available for contact with family members. When staff break the news of death in a sympathetic manner and provide explanations, family members are grateful. Otherwise, feelings of anger, frustration, and confusion can add to their grief (Walsh & McGoldrick, 2004). Crisis intervention services are needed to help survivors cope with sudden death.

© JOHN BIRDSALL/ALAMY

Dying in intensive care is a depersonalizing experience unique to technologically sophisticated societies. In such settings, medical responses supersede privacy and communicating with patient and family.

Nicholas died in an ICU focused on preventing death in patients whose condition can worsen quickly. Privacy and communication with the family were secondary to monitoring his condition. To avoid disruption of nurses' activities, Giselle and Sasha could be at Nicholas's side only at scheduled times. Dying in intensive care—an experience unique to technologically sophisticated societies—is especially depersonalizing for patients like Nicholas, who linger between life and death while hooked to machines, sometimes for weeks or months.

Cancer patients, who account for most cases of prolonged dying, typically die in general or specialized cancer-care hospital units. When hospitalized for a long time, they reach out for help with physical and emotional needs, too often with mixed success. In these hospital settings, as in ICUs, a conflict of values is apparent (Hillman, 2011). The tasks associated with dying must be performed efficiently so all patients can be served and health professionals are not drained emotionally by repeated attachments and separations.

Although hospital comprehensive treatment programs aimed at easing physical, emotional, and spiritual suffering at the end of life have increased steadily over the past decade, one-third of U.S. hospitals still do not have them (Dumanovsky et al., 2016). And because most U.S. and Canadian medical schools do not offer even a single pain-focused course (usually an elective), few doctors and nurses are specially trained in managing pain in chronically ill and dying people (Horowitz, Gramling, & Quill, 2014). At present, many people die in painful, frightening, and depersonalizing hospital conditions, without their wishes being met.

## Nursing Home

Though deaths in U.S. nursing homes—mostly very old patients—are common, care emphasizes rehabilitation rather than high-quality terminal care. Too often, residents' end-of-life preferences are not gathered and recorded in medical records. The few studies that have addressed what it is like to die in nursing homes concur that many patients suffer from inattention to their emotional and spiritual needs, high levels of untreated pain, and aggressive end-of-life medical intervention (Miller, Lima, & Thompson, 2015).

The hospice approach—which we consider next—aims to reduce profound caregiving failures in hospitals and nursing homes. When combined with hospice, nursing home care of the dying improves greatly in pain management, prevention of hospitalizations, emotional and spiritual support, and family satisfaction (Zheng et al., 2012, 2015). But referrals of dying nursing-home residents to hospice, though increasing, are often not made—or made too late to be useful.

## The Hospice Approach

In medieval times, a *hospice* was a place where travelers could find rest and shelter. In the nineteenth and twentieth centuries, the word referred to homes for dying patients. Today, **hospice** is not a place but a comprehensive program of support services for

terminally ill people and their families. It aims to provide a caring community sensitive to the dying person's needs so patients and family members can prepare for death in ways that are satisfying to them. Quality of life is central to the hospice approach, which includes these main features:

- The patient and family as a unit of care
- Emphasis on meeting the patient's physical, emotional, social, and spiritual needs, including controlling pain, retaining dignity and self-worth, and feeling cared for and loved
- Care provided by an interdisciplinary team: a doctor, a nurse or home health aide, a chaplain, a counselor or social worker, and a trained volunteer
- The patient kept at home or in an inpatient setting with a homelike atmosphere where coordination of care is possible
- Focus on protecting the quality of remaining life with **palliative, or comfort, care** that relieves pain and other symptoms (nausea, breathing difficulties, insomnia, and depression) rather than prolonging life
- In addition to regularly scheduled care visits, on-call services available 24 hours a day, 7 days a week
- Follow-up bereavement services offered to families in the year after a death

Because hospice care is a philosophy, not a facility, it can be applied in diverse ways. In Great Britain, care in a special hospice inpatient unit, sometimes associated with a hospital, is typical. In the United States, both home and hospice inpatient units are emphasized: About 36 percent of hospice patients die at home, 32 percent in a hospice inpatient unit, 14 percent in a nursing home, 9 percent in another type of residential setting, and 9 percent in a typical hospital room (NHPCO, 2013).

© LUCY NICHOLSON/REUTERS

A son and his dying mother share recollections as he shows her a photograph of her long-ago graduation. By creating opportunities for unpressured closeness and connection, hospice care enhances dying patients' quality of life rather than extending life.

## Biology and Environment

### Music as Palliative Care for Dying Patients

When Peter visits 82-year-old Stuart to play the harp, Stuart reports being transported to an idyllic place with water, children, and trees—far from the lung tumors that will soon take his life. “When Peter plays for me, . . . I am no longer frightened,” Stuart says.

Peter is a specialist in *music thanatology*, an emerging specialty in music therapy that focuses on providing palliative care to the dying through music. He uses his harp, and sometimes his voice, to induce calm and give solace to the dying, their families, and their caregivers. Peter applies music systematically—matching it to each patient’s breathing patterns and other responses, delivering different sounds to uplift or comfort, depending on his assessment of the patient’s moment-by-moment needs.

Research consistently shows that music vigils have diverse benefits. In one investigation, older adults suffering from advanced cancer who had been admitted to a hospital

palliative care unit for end-of-life pain and other symptom management were assigned to one of two groups: standard care plus music therapy or standard care alone. Each music therapy participant experienced four music sessions over the course of 8 to 10 days. Relative to controls, the music group gained in patient-reported relaxation and psychological well-being and declined in emotional and physical symptoms, including anxiety, depression, insomnia, nausea, and shortness of breath (Domingo et al., 2015).

Other evidence indicates that music therapy can reduce pain in dying patients, with one experiment demonstrating the effectiveness of just a single session (Guttsell et al., 2013; Horne-Thompson & Grocke, 2008). Why

LYNN JOHNSON. A SONG FOR THE DYING, 1994. LYNN JOHNSON COLLECTION. MAHIN CENTER FOR ARCHIVES AND SPECIAL COLLECTIONS, OHIO UNIVERSITY LIBRARIES.

Music thanatology focuses on providing palliative care for the dying through music. This practitioner uses her harp, and sometimes her voice, to induce calm and provide solace.

is music helpful in easing end-of-life physical and emotional distress? In patients close to death, hearing typically functions longer than other senses. Consequently, responsiveness to music may persist through the individual’s final days and hours (Berry & Griffie, 2016). For this reason, music vigils may be an especially effective end-of-life therapy.

But hospice programs everywhere have expanded to include a continuum of care, from home to inpatient options, including hospitals and nursing homes. Central to the hospice approach is that the dying person and his or her family be offered choices that guarantee an appropriate death. Contact with others facing terminal illness is a supportive byproduct of many hospice arrangements. And to find out about a comforting, palliative care intervention for patients near death, consult the Biology and Environment box above.

#### LOOK and LISTEN

Contact a nearby hospice program, and find out about the varied ways it delivers comprehensive services to meet the needs of dying patients and their families.

Currently, the United States has over 6,000 hospice programs serving approximately 1.2 million terminally ill patients annually. About 37 percent of hospice patients have cancer. The top non-cancer diagnoses are dementia (15 percent), heart disease (15 percent), and lung disease (9 percent) (NHPCO, 2013). Because hospice care is a cost-effective alternative to expensive life-saving treatments, U.S. government health-care benefits (Medicare and

Medicaid) cover it, as do most private insurance plans. In addition, community and foundation contributions allow many hospices to provide free services to uninsured patients who cannot pay (Hospice Foundation of America, 2016). Consequently hospice is affordable for most dying patients and their families. Hospices also serve dying children—a tragedy so devastating that social support and bereavement intervention are vital.

Besides reducing patient physical suffering, hospice contributes to improved family functioning. The majority of patients and families report high satisfaction with quality of care. Compared to other dying patients, those who receive hospice care experience better pain management, enhanced sense of social support, higher quality of life, longer survival, greater correspondence between their preferred and actual place of death, and reduced medical expenditures (Candy et al., 2011; Churchman et al., 2014; Connor et al., 2007). Six months to two years after their loved one’s death, family members experiencing hospice score higher than their nonhospice counterparts in psychological well-being (Ragow-O’Brien, Hayslip, & Guarnaccia, 2000; Wright et al., 2008).

As a long-range goal, hospice organizations are striving for broader acceptance of their patient- and family-centered approach. Culturally sensitive approaches are needed to reach more ethnic minority patients, who are far less likely than white

patients to participate in hospice (NHPCO, 2013). Canada has a Web-based hospice outreach service, the Canadian Virtual Hospice ([www.virtualhospice.ca](http://www.virtualhospice.ca)), to support patients, families, and care providers—whether or not they are part of a hospice program—with information, resources, and connections to others with similar concerns.

In developing countries, where millions of children and adults die of cancer and other devastating illnesses each year, community-based teams working under a health professional's supervision are making progress in delivering hospice and palliative care services. But they face many obstacles, including lack of funding, pain-relieving drugs, and professional and public education about hospice (WPCA, 2014). As a result, they are “islands of excellence,” accessible to far too few patients and families.

## Ask yourself

**CONNECT** Reread the description of Sofie's mental and emotional reactions to dying on pages 653 and 654. Then review the story of Sofie's life on pages 3–4 in Chapter 1. How were Sofie's responses consistent with her personality and lifelong style of coping with adversity?

**APPLY** When 5-year-old Timmy's kidney failure was diagnosed as terminal, his parents couldn't accept the tragic news. Their hospital visits became shorter, and they evaded his anxious questions. Eventually, Timmy blamed himself. He died with little physical pain, but alone, and his parents suffered prolonged guilt. How could hospice care have helped Timmy and his family?

**REFLECT** If you were terminally ill, where would you want to die? Explain.

## The Right to Die

**19.5** Discuss end-of-life medical practices, along with ethical controversies surrounding them.

In 1976, the parents of Karen Ann Quinlan, a young woman who had fallen into an irreversible coma after taking drugs at a party, sued to have her respirator turned off. The New Jersey Supreme Court, invoking Karen's right to privacy and her parents' power as guardians, complied with this request. Although Karen was expected to die quickly, she breathed independently, continued to be fed intravenously, and lived another 10 years in a persistent vegetative state.

In 1990, 26-year-old Terri Schiavo's heart stopped briefly, temporarily cutting off oxygen to her brain. Like Karen, Terri lay in a persistent vegetative state. Her husband and guardian, Michael, claimed that she had earlier told him she would not want to be kept alive artificially, but Terri's parents disagreed. In 1998, the Florida Circuit Court granted Michael's petition to have Terri's feeding tube removed. In 2001, after her parents had exhausted their appeals, the tube was taken out. But on the basis of contradictory medical testimony, Terri's parents convinced a

circuit court judge to order the feeding tube reinserted, and the legal wrangling continued. In 2002, Michael won a second judgment to remove the tube.

By that time, publicity over the case and its central question—who should make end-of-life decisions when the patient's wishes are unclear—had made Terri a political issue. In 2003, the Florida legislature passed a law allowing the governor to stay the circuit court's order to keep Terri alive, but on appeal, the law was declared unconstitutional. In 2005, the U.S. Congress entered the fray, passing a bill that transferred Terri's fate to the U.S. District Court. When the judge refused to intervene, the feeding tube was removed for a third time. In 2005—15 years after losing consciousness—Terri Schiavo died. The autopsy confirmed the original persistent vegetative state diagnosis: Her brain was half normal size.

Before the 1950s, the right to die was of little concern because medical science could do little to extend the lives of terminally ill patients. Today, medical advances mean that the same procedures that preserve life can prolong inevitable death, diminishing both quality of life and personal dignity.

The Quinlan and Schiavo cases—and others like them—brought right-to-die issues to the forefront of public attention. Today, all U.S. states have laws that honor patients' wishes concerning withdrawal of life-sustaining treatment in cases of terminal illness and, sometimes, in cases of a persistent vegetative state, thereby permitting the patient to die naturally. But no uniform right-to-die policy covering other situations exists, and heated debate persists over how to handle the diverse circumstances in which patients and family members make requests. The various practices that are the focus of right-to-die ethical debates are summarized in Table 19.1. Let's discuss each in turn.

**TABLE 19.1**  
**Ethically Debated End-of-Life Medical Practices**

PRACTICE	DESCRIPTION
Ending life-sustaining treatment	With the terminally ill patient's permission, or the permission of the patient's substitute decision maker, a doctor withholds or withdraws life-sustaining treatment, thereby permitting the patient to die naturally. For example, the doctor does not perform surgery, insert a feeding tube, or administer medication that could prolong life, or the doctor turns off the respirator of a patient who cannot breathe independently.
Medical aid-in-dying	At an incurably ill patient's request, a doctor provides a prescription for a lethal dose of medication that the patient self-administers to end his or her life.
Voluntary euthanasia	At a suffering patient's request, a doctor ends the patient's life in a painless way. For example, the doctor administers a lethal dose of medication.
Involuntary euthanasia	A doctor ends a suffering patient's life by some medical means, such as a lethal dose of medication, without the patient's consent.

## Ending Life-Sustaining Treatment

Do you think Terri Schiavo should have been allowed to die sooner? Was it right for Nicholas's doctors to turn off his respirator at Giselle's request? When an Alzheimer's victim has lost all awareness and bodily functions, should life support be withheld?

Surveys reveal that more than 70 percent of U.S. adults and 95 percent of physicians support the right of patients or family members to end treatment when there is no hope of recovery (Curlin et al., 2008; Pew Research Center, 2006). In 1986, the American Medical Association endorsed withdrawing all forms of treatment from the terminally ill when death is imminent and from those in a permanent vegetative state. Consequently, ending treatment in situations like those just described is now widely practiced as part of ordinary medical procedure, in which doctors exercise professional judgment.

Still, a minority of Americans oppose the practice. Religious denomination has surprisingly little effect on people's opinions. For example, most Catholics hold favorable views, despite slow official church acceptance because of fears that ending treatment might be a first step toward government-approved mercy killing. However, ethnicity makes a difference: Many more African Americans than European Americans say they desire all medical means possible, regardless of the patient's condition, and African Americans more often receive life-sustaining intervention, such as feeding tubes (Haley, 2013; Wicher & Meeker, 2012). Their reluctance to forgo treatment reflects strong religious belief in the power of God to promote healing, mistrust of the health-care system, and limited knowledge of how to express end-of-life treatment preferences.

Because of controversial court cases like Terri Schiavo's, many doctors and health-care institutions are unwilling to withhold or withdraw treatment without legal protection. In the absence of consensus on the practice, people can best ensure that their wishes will be followed by preparing an **advance medical directive**—a written statement of desired medical treatment should they become incurably ill. U.S. states recognize two types of advance directives: a *living will* and a *durable power of attorney for health care*. Sometimes these are combined into one document.

In a **living will**, people specify the treatments they do or do not want in case of a terminal illness, coma, or other near-death situation (see Figure 19.2). For example, a person might state that without reasonable expectation of recovery, he or she should not be kept alive through medical intervention of any kind. In addition, a living will sometimes specifies that pain-relieving medication be given, even though it might shorten life. In Sofie's case, her doctor administered a powerful narcotic to relieve labored

breathing and quiet her fear of suffocation. The narcotic induced unconsciousness and suppressed respiration, causing death to occur hours or days earlier than if the medication had not been prescribed. Such palliative care is accepted as appropriate and ethical medical practice.

Although living wills help ensure personal control, they do not guarantee it. Recognition of living wills is usually limited to patients who are terminally ill or are otherwise expected to die shortly. Only a few U.S. states cover people in a persistent vegetative state or aging adults who linger with many chronic problems, including Alzheimer's disease, because these conditions are not classified as terminal. Even when terminally ill patients have living wills, doctors often do not follow them for a variety of reasons (Saitta & Hodge, 2013). These include fear of lawsuits, their own moral beliefs, failure to inquire about patients' directives, and inaccessibility of those directives—for example, located in the family safe or family members unaware of them.

**LIVING WILL**

THIS DECLARATION is made this \_\_\_\_\_ day of \_\_\_\_\_, 20 \_\_\_\_ .

I, \_\_\_\_\_, being of sound mind, willfully and voluntarily make known my desires that my moment of death shall not be artificially postponed. If at any time I should have an incurable and irreversible injury, disease, or illness judged to be a terminal condition by my attending physician who has personally examined me and has determined that my death is imminent except for death delaying procedures, I direct that such procedures which would only prolong the dying process be withheld or withdrawn, and that I be permitted to die naturally with only the administration of medication, sustenance, or the performance of any medical procedure deemed necessary by my attending physician to provide me with comfort care.

In the absence of my ability to give directions regarding the use of such death delaying procedures, it is my intention that this declaration shall be honored by my family and physician as the final expression of my legal right to refuse medical or surgical treatment and accept the consequences from such refusal.

Signed: \_\_\_\_\_

City, County and State of Residence: \_\_\_\_\_

\_\_\_\_\_

\_\_\_\_\_

*The declarant is personally known to me and I believe him or her to be of sound mind. I saw the declarant sign the declaration in my presence (or the declarant acknowledged in my presence that he or she had signed the declaration) and I signed the declaration as a witness in the presence of the declarant. At the date of this instrument, I am not entitled to any portion of the estate of the declarant according to the laws of intestate succession or, to the best of my knowledge and belief, under any will of declarant or other instrument taking effect at declarant's death, or directly financially responsible for declarant's medical care.*

Witness: \_\_\_\_\_

Witness: \_\_\_\_\_

**FIGURE 19.2** Example of a living will. This document is legal in the State of Illinois. Each person completing a living will should use a form specific to the U.S. state or Canadian province in which he or she resides because laws vary widely. (Courtesy of Office of the Attorney General, State of Illinois.)

Because living wills cannot anticipate all future medical conditions and can easily be ignored, a second form of advance directive has become common. A **durable power of attorney for health care** authorizes appointment of another person (usually, though not always, a family member) to make health-care decisions on one's behalf. It generally requires only a short signed and witnessed statement like this:

I hereby appoint [name] as my attorney-in-fact (my "agent") to act for me and in my name (in any way I could act in person) to make any and all decisions for me concerning my personal care, medical treatment, hospitalization, and health care and to require, withhold, or withdraw any type of medical treatment or procedure, even though my death may ensue. (Courtesy of Office of the Attorney General, State of Illinois)

The durable power of attorney for health care is more flexible than the living will because it permits a trusted spokesperson to confer with the doctor as medical circumstances arise. Because authority to speak for the patient is not limited to terminal illnesses, more latitude exists for dealing with unexpected situations. And for couples who are not legally married, the durable power of attorney can ensure the partner's role in decision making and in advocating for the patient's health-care needs.

Whether or not a person supports ending treatment when natural death is imminent, it is important to have a living will, durable power of attorney, or both, because most deaths occur in hospitals or long-term care facilities. Yet only 45 percent of Americans over age 40 have executed such documents, perhaps because of widespread uneasiness about bringing up the topic of death, especially with relatives. The percentage with advance directives increases with age; nearly 55 percent of adults over age 65 have them (Government Accountability Office, 2015). To encourage people to make decisions about potential treatment while they are able, U.S. federal law now requires that all medical facilities receiving federal funds provide information at

KATARZYNA BIALASIEWICZ/ISTOCK/GETTY IMAGES PLUS

A terminally ill patient discusses a durable power of attorney with his son and daughter. This advance directive authorizes a trusted spokesperson to make health-care decisions and helps ensure that one's desires will be granted.

admission about state laws and institutional policies on patients' rights and advance directives.

As happened with Karen Quinlan and Terri Schiavo, health professionals—when uncertain about a patient's intent and fearing liability—will probably decide to continue treatment regardless of cost and a person's prior oral statements. Perhaps for this reason, some U.S. states permit appointment of a health-care proxy, or substitute decision maker, if a patient failed to provide an advance medical directive while competent. Proxies are an important means of covering children and adolescents, who cannot legally execute advance medical directives.

## Medical Aid-in-Dying

Shortly after her wedding in 2012, Brittany Maynard began experiencing headaches that increased in severity. In early 2014, at age 29, she was diagnosed with an aggressive, incurable form of brain cancer. At first, doctors estimated that Brittany had several years left to live—an exceedingly short time to any 29-year-old. But additional tests revealed that the cancer was spreading rapidly, causing her medical team to revise its forecast to just six months.

No available treatment could save Brittany's life, and treatments doctors recommended to extend it, she concluded, would have destroyed her quality of life. So Brittany decided to live as long as she could and then, with the aid of prescription sleeping medication, end her own life legally and gently before suffering became unbearable—a choice she discussed with her husband, Dan, who respected it.

In **medical aid-in-dying**, at an incurably ill patient's request, a doctor provides a prescription for a lethal dose of drugs, which the patient self-administers to end his or her life. Brittany and Dan lived in California, where at the time the practice was illegal, so they uprooted to Oregon, where doctors could, by law, prescribe drugs to assist terminally ill patients in ending their own lives gently. She spent her remaining days doing what she loved most—in the outdoors, including visiting several national parks, with people closest to her. She also advocated for terminally ill patients' right to choose when to die, explaining that having that choice gave her the sense of peace that enabled her to live fully.

As Brittany's brain seizures intensified and she experienced sleeplessness, nausea, and medication-resistant pain, she worried about waiting too long—that the growing tumor would cause sensory, cognitive, verbal, and motor losses and rob her of her autonomy. On November 1, 2014, she took the medication and died peacefully within 30 minutes, surrounded by her family and dearest friends.

In the United States, medical aid-in-dying is legal in five states: Oregon, Washington, Montana, Vermont, and—as of 2016—California. Oregon, the first state to pass legislation, in 1998, limits the practice to patients who are incurably ill; they need not be in unbearable pain. Patients must have two doctors agree that they have six months or less to live, and must wait

© RICH PEDRONCELLI/AP IMAGES

At a right-to-die rally in Sacramento, California, Dan Diaz holds a picture of his late wife, Brittany Maynard, while hugging a terminally ill cancer patient who spoke at the event. Dan's advocacy was instrumental in the passage of California's End of Life Option Act, which legalized medical aid-in-dying and went into effect in 2016.

15 days following an oral request and 48 hours following a written request before being given the drugs. In Washington, Vermont, and California, legal requirements resemble Oregon's (Emanuel et al., 2016). Montana has no specified requirements because legalization resulted from a court ruling, not legislation.

Six other nations—Belgium, the Netherlands, Luxembourg, Switzerland, Colombia, and Canada—have passed medical aid-in-dying legislation. Although patients in these countries need not be terminally ill, they must be experiencing “unbearable” physical or mental suffering without prospect for improvement.

Over the past decade, about 55 percent of Americans have expressed approval of medical aid-in-dying for patients with a terminal illness, a rate that rose to 68 percent following widespread publicity of Brittany Maynard's story (Dugan, 2015). In a review of U.S., Canadian, and Western European surveys, level of support among terminally ill patients was about the same as for the general public, with one-third of patients saying they would consider it for themselves (Hendry et al., 2012). People who support the practice, as well as patients who request it, tend to be higher in SES, white, and less religious.

Oregon has the most extended, detailed records on patients who ended their own lives by taking a legal, physician-prescribed dose of drugs. Their numbers have risen over time, though they account for less than one-half of 1 percent of all deaths. Most (68 percent) were age 65 or older, and the overwhelming majority (90 percent) were enrolled in hospice and died at home. Their most common diagnosis (78 percent) was cancer. As Figure 19.3 shows, patients' most frequently expressed reasons for request-

ing medical aid-in-dying were loss of autonomy, decreasing ability to participate in activities that make life enjoyable, loss of dignity, and loss of control of bodily functions (Oregon Public Health Division, 2016). Inadequate pain control was of far less concern; most knew they had access to palliative care through hospice.

In medical aid-in-dying, the final act is solely the patient's, reducing the possibility of coercion. Still, intense disagreement surrounds the practice. Until recently, it was widely referred to as *physician-assisted suicide*. But proponents of legalization point out that terminally ill patients who gain access to medical aid-in-dying under current U.S. state laws are not suicidal; they do not want to die, nor are they motivated by emotional distress or mental illness. Each state statute specifies that medical aid-in-dying does not constitute suicide and that the patient's incurable disease must be entered as the cause of death on the death certificate.

Opponents of legalization claim that in an atmosphere of high family-caregiving burdens and pressure to contain health-care expenditures (see Chapter 17), legalizing medical aid-in-dying poses risks. For example, patients might seek it out of escalating health-care costs or fear of becoming a burden to their families. Trained as healers, U.S. doctors are less favorable than the general public, but their openness to medical aid-in-dying has grown. In a recent survey of more than 17,000 physicians representing 28 medical specialties, 54 percent indicated that they would support an incurably and terminally ill patient's decision to end his or her life and would want the same option to be available for themselves (Kane, 2014).

**FIGURE 19.3** Reasons given by Oregon patients requesting medical aid-in-dying. Responses gathered between 1998 and 2014 from over 850 patients who ended their own lives under the Oregon Death with Dignity Act revealed that the majority were concerned about loss of autonomy, reduced capacity to engage in activities making life enjoyable, and loss of dignity. (Based on Oregon Public Health Division, 2016.)

The American Academy of Hospice and Palliative Medicine (2016), though taking a position of neutrality on legalization, has expressed concern about aid-in-dying becoming part of routine medical practice. It advises great caution on the part of doctors practicing in regions where medical aid-in-dying is legal, including making sure before engaging in it that the following conditions are met:

- The patient has access to the best possible palliative care and will continue to receive such care throughout the dying process.
- The patient has full decision-making capacity, requests medical aid-in-dying voluntarily, and has a limited life expectancy; health-care financial pressures and coercive influences from family members or others play no role.
- All reasonable alternatives have been considered and implemented, if acceptable to the patient.
- The practice is consistent with the doctor's fundamental values, and he or she is willing to participate. (If not, the doctor should recommend transfer of care, while taking into account professional obligations of nonabandonment.)

Still, evidence confirms that palliative care does not relieve pain in all cases, as it failed to do for Brittany. Nor does palliative care address dying patients' concerns about loss of autonomy and dignity, including the desire of some to avoid an extended period of palliative sedation once suffering intensifies (Kon, 2011). Finally, because the life-ending act is solely the patient's, many supporters of medical aid-in-dying believe that legalizing it is preferable to legalizing voluntary euthanasia, the practice we take up next.

## Voluntary Euthanasia

In **voluntary euthanasia**, at a patient's request, a doctor actively takes the patient's life in a painless way for the purpose of relieving suffering. The practice, a form of mercy killing, is a criminal offense in all U.S. states and most other countries. But public support for voluntary euthanasia grew over the 1980s and 1990s, reaching two-thirds of the American population, and has since stabilized (Emanuel et al., 2016; McCarthy, 2014). In Belgium, the Netherlands, Luxembourg, and Canada, where voluntary euthanasia is legal, public approval is similar to or higher than in the United States. In Eastern European countries where most of the population is religious, approval rates are lower, generally around 45 percent (Cohen et al., 2014).

In the United States and Western European nations where voluntary euthanasia is illegal, the courts are usually lenient with doctors who engaged in it with patients near death and suffering profoundly, generally granting suspended sentences or probation. Nevertheless, attempts to legalize the practice have prompted heated controversy. Supporters believe it represents the most compassionate option for terminally ill people enduring

great suffering. Opponents stress the moral difference between "letting die" and "killing" and argue that permitting doctors to take patients' lives may impair people's trust in health professionals. Finally, a fear exists that legalizing the practice—even when strictly monitored to ensure it does not arise out of depression, loneliness, coercion, or a desire to relieve the burden of caregiving on others—could result in broadening of euthanasia. Initially limited to the terminally ill, it might be applied involuntarily to the frail and disabled—outcomes that most people find unacceptable and immoral.

Will legalizing voluntary euthanasia lead us down a "slippery slope" to the killing of vulnerable people who either did not ask to die or were not mentally fit to make the decision? In Canada and Western Europe, safeguards are in place to prevent such deaths. In the Netherlands, for example, legal practice of euthanasia requires that physical or mental suffering be severe, with no prospect of relief; the patient's decision be well-informed and stable over time; all other options for care have been exhausted or refused; and a second doctor be consulted. These restrictions appear to have sharply reduced instances of *involuntary euthanasia* (without patient consent). Prior to legalization, Dutch physicians reported administering lethal drugs without patient approval in nearly 1 percent of deaths, a rate that declined fourfold after legalization. A substantial decrease also occurred in Belgium, where before legalization the doctor-reported incidence of involuntary euthanasia was as high as 3 percent (Chambaere et al., 2015; Onwuteaka-Philipsen et al., 2012).

Still, intense disagreement persists over voluntary euthanasia. A survey of Dutch doctors revealed that 86 percent dread the emotional burden of performing it (Van der Heide & Onwuteaka-Philipsen, 2012, as cited by Emanuel et al., 2016). Patients with dementia and mental illness, terminally ill minors, and older adults who say they are "tired of life" are of special concern. Even where voluntary euthanasia is legal in restricted circumstances, challenges in monitoring and regulating it remain. Helping suffering patients who yearn for death poses profound ethical and legal dilemmas.

## Ask yourself

**APPLY** Thinking ahead to the day she dies, Noreen imagines a peaceful scene in which she says goodbye to loved ones. What social and medical practices are likely to increase Noreen's chances of dying in the manner she desires?

**APPLY** Ramón is certain that, if he ever became terminally ill, he would want doctors to halt life-saving treatment. To best ensure that his wish will be granted, what should Ramón do?

**REFLECT** If you were terminally ill, would you consider medical aid-in-dying or voluntary euthanasia? If so, under what conditions? Explain.

## Bereavement: Coping with the Death of a Loved One

**19.6** Describe the process of grieving, factors that contribute to individual variations, and bereavement interventions.

Loss is an inevitable part of existence throughout the lifespan. Even when change is for the better, we must let go of some aspects of experience so we can embrace others. In this way, our development prepares us for profound loss.

**Bereavement** is the experience of losing a loved one by death. The root of this word means “to be robbed,” suggesting unjust and injurious theft of something valuable. Consistent with this image, we respond to loss with **grief**—intense physical and psychological distress. When we say someone is grief-stricken, we imply that his or her total way of being is affected.

Because grief can be overwhelming, cultures have devised ways of helping their members move beyond it to deal with the life changes demanded by death of a loved one. **Mourning** is the culturally specified expression of the bereaved person’s thoughts and feelings. Customs—such as gathering with family and friends, dressing in black, attending the funeral, and observing a prescribed mourning period with special rituals—vary greatly among societies and ethnic groups. But all have in common the goal of helping people work through their grief and learn to live in a world that does not include the deceased.

Clearly, grief and mourning are closely linked—in everyday language, we often use the two words interchangeably. Let’s look closely at how people respond to the death of a loved one.

### Grief Process

Theorists formerly believed that bereaved individuals, both children and adults, moved through three phases of grieving—avoidance, confrontation, and restoration—each characterized by a different set of responses (Bowlby, 1980; Rando, 1995). In reality, however, people vary greatly in emotional reactions, behavior, and timing. An estimated 60 to 70 percent experience mild distress that resolves within a few months. Another 15 to 25 percent experience moderate distress, depression, and difficulties in everyday functioning and recover gradually, usually within a year. Only about 5 to 15 percent experience severe, prolonged distress, depression, and lack of acceptance of the death that persists for years, impairing physical and mental health—termed **complicated grief** (Bonanno, 2004; Bonanno, Westphal, & Mancini, 2011; Newson et al., 2011). As these findings reveal, the typical response to loss of a loved one is resilience.

Grievers generally move back and forth between emotional reactions, with many ups and downs. Rather than phases, the grief process is best conceived as a set of *tasks*—actions the person must take to recover and return to a fulfilling life: (1) to

accept the reality of the loss, (2) to work through the pain of grief, (3) to adjust to a world without the loved one, and (4) to develop an inner bond with the deceased and move on with life (Worden, 2009). According to this view, people can take active steps to overcome grief—a powerful remedy for the distress that the bereaved often experience.

**Avoidance and Confrontation.** On hearing the news, many survivors react with shock followed by disbelief—a numbed feeling that serves as “emotional anesthesia” while the person begins the first task of grieving: becoming aware of and confronting the loss. Avoidance is generally short-lived, lasting from hours to weeks. Those who get stuck in it—for example, by ruminating about their own loss-related problems as a way to distract themselves from the reality of the death—are at risk for intense, long-lasting grief reactions that interfere with recovery (Eisma et al., 2013).

As grievors confront the reality of the death, they may experience a cascade of emotional reactions, including anxiety, sadness, protest, anger, helplessness, frustration, abandonment, and yearning for their loved one. Typical responses include obsessively reviewing the circumstances of death, asking how it might have been prevented, and searching for meaning in it (Neimeyer, 2001). In addition, grief-stricken people may be absentminded, unable to concentrate, and preoccupied with thoughts of the deceased, and may experience loss of sleep and appetite. Self-destructive behaviors, such as taking drugs or driving too fast, may occur. Most of these responses are symptoms of depression—a common component of grieving.

Although confrontation is difficult, it enables mourners to grapple with the second task: working through the pain of grief. Each surge of anguish that results from an unmet wish to be reunited with the deceased brings them closer to accepting that the loved one is gone and that a cherished relationship must be transformed from a physical presence to an inner representation. As a result, they make progress on the third task: adjusting to a world in which the deceased is missing.

**Restoration.** Adapting to loss is more than an internal, emotional task. The bereaved must also deal with stressors that are secondary outcomes of the death—overcoming loneliness by reaching out to others; mastering skills (such as finances or cooking) that the deceased had performed; reorganizing daily life without the loved one; and revising one’s identity from “spouse” to “widow” or from “parent” to “parent of a deceased child.”

According to a perspective called the **dual-process model of coping with loss**, effective coping requires people to oscillate between dealing with the emotional consequences of loss and attending to life changes, which—when handled successfully—have restorative, or healing, effects (Hansson & Stroebe, 2007; Stroebe & Schut, 1999, 2010). Moving back and forth offers temporary distraction and relief from painful grieving. Much

research indicates that confronting grief without relief has severe negative consequences for physical and mental health (Corr & Corr, 2007). Consistent with the dual-process model, in a study that assessed widowed older adults at 6, 18, and 48 months after the death of their spouses, both loss-oriented and restoration-oriented activities occurred throughout bereavement. As predicted, restoration-oriented activities—such as visiting friends, attending religious services, and volunteering—reduced distress (Richardson, 2007). Using the dual-process model, one approach to intervention for grieving individuals addresses both emotional and life-change issues, alternating between them.

As grief subsides, emotional energies increasingly shift toward the fourth task—forging a symbolic bond with the deceased and moving on with life by meeting everyday responsibilities, investing in new activities and goals, strengthening old ties, and building new relationships. On certain days, such as family celebrations or the anniversary of death, grief reactions may resurface and require attention, but they do not interfere with a healthy, positive approach to life.

In fact, throughout the grief process, resilient individuals report experiencing both positive and negative emotions, with happiness and humor aiding in coping with grief (Ong, Bergeman, & Bisconti, 2004). In an investigation of several hundred people age 50 and older whose spouse or partner had died within the previous six months, 90 percent agreed that positive emotion in daily life is important, and more than 75 percent said they had experienced humor, laughter, or happiness during the past week. The greater participants' valuing and experience of positive emotion, the better their bereavement adjustment (Lund et al., 2008–2009). Expressions of happiness can be viewed as a restoration-oriented activity, offering distraction from grieving and strengthening bonds with others.

## Personal and Situational Variations

Like dying, grieving is affected by many factors, including personality, coping style, and religious and cultural background. Gender differences are also evident. Compared with women, men typically express distress and depression less directly and seek social support less readily (Doka & Martin, 2010).

Furthermore, the quality of the person's relationship with the deceased is important. An end to a loving, fulfilling bond often leads to anguished confrontation with loss, but this soon resolves. The dissolution of a conflict-ridden, ambivalent tie, in contrast, is more likely to leave a long-term residue of anger, guilt, and regret (Abakoumkin, Stroebe, & Stroebe, 2010; Bonanno et al., 2002; Mikulincer & Shaver, 2008). And end-of-life care makes a difference: Widowed older adults whose spouses experienced a painful death report more anxiety, intrusive thoughts, and yearning for the loved one six months later (Carr, 2003).

Circumstances surrounding the death—whether it is sudden and unanticipated or follows a prolonged illness—also shape mourners' responses. The nature of the lost relationship and the timing of the death within the life course make a difference as well.

## Sudden, Unanticipated Deaths versus Prolonged, Expected Deaths.

In instances of sudden, unexpected deaths—usually the result of murder, suicide, war, accident, or natural disaster—avoidance may be especially pronounced and confrontation highly traumatic because shock and disbelief are extreme. In a survey of a large representative sample of 18- to 45-year-olds in Detroit, the trauma most often reported as prompting an intense, debilitating stress reaction was the sudden, unanticipated death of a loved one (Breslau et al., 1998). In contrast, during prolonged dying, the bereaved person has had time to engage in **anticipatory grieving**—acknowledging that the loss is inevitable and preparing emotionally for it. Survivors may feel less overwhelmed immediately following the death (Johansson & Grimby, 2013). Still, they may be vulnerable to persistent anxiety due to long-term stressors, such as highly demanding caregiving and having watched a loved one suffer from a debilitating illness.

Adjusting to a sudden death is easier when the survivor understands the reasons for it. This barrier to confronting loss is tragically apparent in cases of sudden infant death syndrome (SIDS), in which doctors cannot tell parents exactly why their baby died (see Chapter 3, page 106). That death seems “senseless” also complicates grieving after suicides, terrorist attacks, school and drive-by shootings, natural disasters, and motor vehicle fatalities. In Western societies, people tend to believe that momentous events should be comprehensible and nonrandom (Lukas & Seiden, 2007). A death that is sudden and unexpected can threaten basic assumptions about a just, benevolent, and controllable world.

Suicide, particularly that of a young person, is especially hard to bear. Compared with survivors of other sudden deaths, people grieving a suicidal loss are more likely to conclude that they contributed to or could have prevented it—self-blame that can trigger profound guilt and shame. These reactions are likely to be especially intense and persistent when the griever's culture or religion condemns suicide as immoral (Dunne & Dunne-Maxim, 2004). Individuals who have survived a suicide typically score higher than those who have experienced other types of losses in feelings of guilt and shame, sense of rejection by the deceased, and desire to conceal the cause of death (Dyregrov et al., 2014; Sveen & Walby, 2008). Typically, recovery from grief after a suicide is prolonged.

## Parents Grieving the Loss of a Child.

The death of a child, whether unexpected or foreseen, is the most difficult loss an adult can face. Children are extensions of parents' feelings about themselves—a vital part of their identity and focus of their hopes and dreams, including their sense of immortality (Price & Jones, 2015). Also, because children depend on, admire, and appreciate their parents in a deeply gratifying way, they are an unmatched source of love. Finally, the death of a child is unnatural: Children are not supposed to die before their parents.

Parents who have lost a child often report considerable distress and resurgence of grief for years. The guilt and sense of unfairness triggered by outliving their child frequently become

AP IMAGES/MANU BRABO

A father weeps while holding the body of his son, killed during the Syrian armed conflict. The death of a child, whether unexpected or foreseen, is the most difficult loss an adult can face.

tremendous burdens. Compared to fathers, mothers report more intense distress, especially when they lack opportunities to share thoughts and feelings with their spouse (Lang, Gottlieb, & Amsel, 1996; Moriarty, Carroll, & Cotroneo, 1996). (Recall that men generally grieve less openly than women.) These emotional consequences negatively affect parents' lives and likely contribute to the higher divorce rate among bereaved parents than other parents (Lyngstad, 2013; Wheeler, 2001). Risk of marital breakup tends to strengthen over time and is greatest for couples whose relationship was problematic before the child's death.

If parents can reorganize the family system and reestablish a sense of life's meaning through valuing the lost child's impact on their lives, and investing in other children and activities, then the result can be firmer family commitments and personal growth. The process, which can be lengthy, is associated with improved physical and mental health and gains in marital satisfaction (Murphy, 2008; Price et al., 2011). Five years after her son's death, one parent reflected on her progress:

I was afraid to let go [of my pain, which was] a way of loving him.... Finally I had to admit that his life meant more than pain, it also meant joy and happiness and fun—and living.... When we release pain we make room for happiness in our lives. My memories of S. became lighter and more spontaneous. Instead of hurtful, my memories brought comfort, even a chuckle.... realized S. was still teaching me things. (Klass, 2004, p. 87)

**Children and Adolescents Grieving the Loss of a Parent or Sibling.** The loss of an attachment figure has long-term consequences for children. When a parent dies, children's

basic sense of security and being cared for is threatened. And the death of a sibling not only deprives children of a close emotional tie but also informs them, often for the first time, of their own vulnerability.

Children grieving a family loss describe frequent crying, trouble concentrating in school, sleep difficulties, headaches, and other physical symptoms several months to years after a death. And clinical studies suggest that persistent depression, anxiety, angry outbursts, social withdrawal, loneliness, and worries about dying themselves are common (Luecken, 2008; Marshall & Davies, 2011). At the same time, many children say they have actively maintained mental contact with their dead parent or sibling, dreaming about and speaking to them regularly (Martinson, Davies, & McClowry, 1987; Silverman & Nickman, 1996). These images, reported by bereaved adults as well, seem to facilitate coping with loss.

Cognitive development contributes to the ability to grieve. For example, children who have not yet acquired a biological understanding of death may believe the dead parent left voluntarily, perhaps in anger, and that the other parent may also disappear. For these reasons, young children need careful, repeated explanations assuring them that the parent did not want to die and was not angry at them (Christ, Siegel, & Christ, 2002). Keeping the truth from children about an impending death can lead to profound regret. One 8-year-old who learned only a half-hour in advance that his sick brother was dying reflected, "If only I'd known, I could have said goodbye."

Regardless of children's level of understanding, honesty, affection, and reassurance help them tolerate painful feelings of loss. Grief-stricken school-age children are usually more willing than adolescents to confide in parents. To appear "normal," teenagers tend to keep their grieving from both adults and peers (Barrera et al., 2013). Consequently, they are more likely than children to become depressed or to escape from grief through acting-out behavior.

Overall, effective parenting—warm, empathetic support combined with rational discipline—fosters adaptive coping and positive long-term adjustment in both children and adolescents (Luecken, 2008). Peer support is also helpful, though girls experience it more often than boys, due to greater closeness and self-disclosure in girls' friendships (LaFreniere & Cain, 2015).

### Adults Grieving the Loss of an Intimate Partner.

Recall from Chapter 18 that after the death of a spouse, adaptation to widowhood varies greatly, with age, gender, social support, and personality making a difference. After a period of grieving, most widowed older adults in Western nations fare well, while younger individuals display more negative outcomes (see page 628 to review). Older widows and widowers have many more contemporaries in similar circumstances. And most have already attained important life goals or adjusted to the fact that some goals will not be attained.

In contrast, loss of a spouse or partner in early or middle adulthood is a nonnormative event that profoundly disrupts life plans. Interviews with a large, nationally representative sample

of U.S. adults who had been widowed from less than 1 to 64 years previously (typically in middle adulthood) revealed that thoughts about and conversations with the lost spouse occurred often in the first few years, then declined gradually (Carnelley et al., 2006). But they did not reach their lowest level for several decades, when the typical respondent still thought about the deceased partner once every week or two and conversed with him or her about once a month.

In addition to dealing with feelings of loss, young and middle-aged widows and widowers often must assume a greater role in comforting others, especially children. They also face the stresses of single parenthood and rapid shrinking of the social network established during their life as a couple.

In countries where same-sex marriage is not legal, the death of a lesbian or gay partner presents unique challenges. When relatives limit or bar the partner from participating in funeral services, the survivor experiences **disenfranchised grief**—a sense of loss without the opportunity to mourn publicly and benefit from others' support—which can profoundly disrupt the grief process (Doka, 2008; Jenkins et al., 2014). Fortunately, gay and lesbian communities provide helpful alternative support in the form of memorial services and other rituals.

**Bereavement Overload.** When a person experiences several deaths at once or in close succession, bereavement overload can occur. Multiple losses deplete the coping resources of even well-adjusted people, leaving them emotionally overwhelmed, severely depressed, and vulnerable to post-traumatic stress symptoms and complicated grief.

Because old age often brings the death of spouse, siblings, and friends in close succession, aging adults are at risk for bereavement overload (Kastenbaum, 2012). But recall from Chapter 18 that compared with young people, older adults are often better equipped to handle these losses. They know that decline and death are expected in late adulthood, and they have had a lifetime of experience through which to develop effective coping strategies.

ALBERTO PIZZOLI/AFP/GETTY IMAGES

At a funeral service, a surviving father and children mourn the loss of family members and friends after a devastating earthquake struck their village in central Italy. Public tragedies can spark bereavement overload, leaving mourners at risk for prolonged, overwhelming grief.

Public tragedies—terrorist attacks, natural disasters, random murders in schools, or widely publicized kidnappings—can spark bereavement overload (Kristensen, Weisaeth, & Heir, 2012; Rynearson & Salloum, 2011). For example, many survivors who lost loved ones, co-workers, or friends in the September 11, 2001, terrorist attacks (including an estimated 3,000 children who lost a parent) experienced repeated images of horror and destruction, which impeded coming to terms with loss. Children and adolescents suffered profoundly—from intense shock, prolonged grief, frequent mental replays of the vicious attack and gruesome outcomes, and fear of the settings in which those events occurred (Nader, 2002; Webb, 2002). The greater the bereaved individual's exposure to the catastrophic death scene, the more severe these reactions.

Funerals and other bereavement rituals, illustrated in the Cultural Influences box on the following page, assist mourners of all ages in resolving grief with the help of family and friends. Those who remain preoccupied with loss and who have difficulty resuming interest in everyday activities benefit from special interventions designed to help them adjust.

## Bereavement Interventions

Sympathy and understanding are sufficient to enable most people to undertake the tasks necessary to recover from grief (see Applying What We Know on page 670). Yet effective support is often difficult to provide, and relatives and friends can benefit from training in how to respond. Sometimes they give advice aimed at hastening recovery or ask questions aimed at managing their own anxiety (“Were you expecting him to die?” “Was she in a lot of pain?”)—approaches that most bereaved people dislike (Kastenbaum, 2012). Listening patiently and assuring the bereaved of “being there” for them—“I’m here if you need to talk,” “Let me know what I can do”—are among the best ways to help.

Bereavement interventions typically encourage people to draw on their existing social network, while providing additional social support through group or individual counseling. Bereaved adults who struggle with and surmount loss often experience stress-related personal growth, including greater awareness of their own strengths, enhanced appreciation of close relationships, and new spiritual insights (Calhoun et al., 2010).

Support groups that bring together grievers who have experienced the same type of loss seem highly effective in promoting recovery. In a program for recently widowed older adults based on the dual-process model of coping with loss, in which group members helped one another resolve grief and master tasks of daily living, participants readily bonded with one another and gained in sense of self-efficacy at managing their own lives (Caserta, Lund, & Rice, 1999). A widow expressed the many lasting benefits:

We shared our anger at being left behind, ... our fright of that aloneness. We shared our favorite pictures, so each of us could know the others' families and the fun we used to have. We shared our feelings of guilt if we had fun ... and found out that

## Cultural Influences

### Cultural Variations in Mourning Behavior

The ceremonies that commemorated Sofie's and Nicholas's deaths—the first Jewish, the second Quaker—were strikingly different. Yet they served common goals: announcing that a death had occurred, ensuring social support, celebrating the life of the deceased, and conveying a philosophy of life after death.

At the funeral home, Sofie's body was washed and shrouded, a Jewish ritual signifying return to a state of purity. Then it was placed in a plain wooden (not metal) coffin, so as not to impede the natural process of decomposition. To underscore the finality of death, Jewish tradition does not permit viewing of the body; it remains in a closed coffin. Traditionally, the coffin is not left alone until burial; in honor of the deceased, the community maintains a day-and-night vigil.

To return the body quickly to the life-giving earth from which it sprang, Sofie's funeral was scheduled as soon as relatives could gather—just three days after death. Sofie's husband and children symbolized their grief by cutting a black ribbon and pinning it to their clothing. The rabbi recited psalms of comfort, followed by a eulogy. The service continued at the graveside. Once the coffin had been lowered into the ground, relatives and friends took turns shoveling earth onto it, each participating in the irrevocable act of burial. The service concluded with the *Kaddish* prayer, which affirms life while accepting death.

At home, the family lit a memorial candle, which burned throughout *shiva*, the seven-day mourning period. A meal of consolation prepared by others followed, creating a warm feeling of community. Jewish custom prescribes that after 30 days, life must gradually return to normal. When a parent dies, the mourning period is extended to 12 months.

In the Quaker tradition of simplicity, Nicholas was cremated promptly. During the next week, relatives and close friends gathered with Giselle and Sasha at their home. Together, they planned a memorial service to celebrate Nicholas's life.

When people arrived on the appointed day, a clerk of the Friends (Quaker) Meeting welcomed them and explained to newcomers the Quaker custom of worshipping silently, with those who feel moved to speak rising at any time to share thoughts and feelings. Many mourners offered personal statements about Nicholas or read poems and selections from Scripture. After concluding comments from Giselle and Sasha, everyone joined hands to conclude the service. A reception for the family followed.

Variations in mourning behavior are vast, both within and across societies. At African-American funerals, for example, grief is expressed freely: Sermons, eulogies, and music are designed to trigger release of deep emotion. Energetic congregant participation, including responsive "Amen," convey to family survivors that the entire community empathizes with them (Collins & Doolittle, 2006). In contrast, the Balinese of Indonesia believe they must remain calm in the face of death so that the gods can hear their prayers. While acknowledging their underlying grief, Balinese mourners work hard to maintain their composure (Rosenblatt, 2008).

Religions also render accounts of the aftermath of death that console both dying and bereaved individuals. Beliefs of tribal and village cultures typically include an elaborate array of ancestor spirits and customs designed to ease the journey of the deceased to the afterlife. The Kalash people of rural Pakistan, who practice the rites of an ancient religion, carry the body to the graveyard on the deceased's bed. Once the grave is filled, mourners invert the bed on it, leaving it for the dead person's use in the next world (Sheikh et al., 2014). Jewish tradition emphasizes personal survival through giving life and care to others. Unlike other Christian groups,

MUHKAMUDDIN/EXPRESS TRIBUNE

Kalash mourners in rural Pakistan surround the body of a community member, who is carried to his grave on his bed. Kalash funeral rites for men include drum beating and dancing, which are intended to ward off any troubles the dead may face on their final journey.

Quakers give little attention to hope of heaven or fear of hell, focusing mainly on "salvation by character"—working for peace, justice, and a loving community.

In recent years, "virtual cemeteries" have arisen on the Internet, which allow postings whenever bereaved individuals feel ready to convey their thoughts and feelings, creation of tributes at little or no cost, and continuous, easy access to the memorial. Most creators of Web tributes choose to tell personal stories, highlighting a laugh, a favorite joke, or a touching moment. Some speak directly to their lost loved one. Guestbooks offer a place for visitors to connect with other mourners (de Vries & Moldaw, 2012). Web cemeteries also provide a means for people excluded from traditional death rituals to engage in public mourning. The following "gravesite" message captures the unique qualities of this highly flexible medium for mourning:

I wish I could maintain contact with you, to keep alive the vivid memories of your impact on my life.... Because I cannot visit your grave today, I use this means to tell you how much you are loved.

## Applying what we Know

### Suggestions for Resolving Grief After a Loved One Dies

SUGGESTION	DESCRIPTION
Give yourself permission to feel the loss.	Permit yourself to confront all thoughts and emotions associated with the death. Make a conscious decision to overcome your grief, recognizing that this will take time.
Accept social support.	In the early part of grieving, let others reach out to you by making meals, running errands, and keeping you company. Be assertive; ask for what you need so people who would like to help will know what to do.
Be realistic about the course of grieving.	Expect to have some negative and intense reactions, such as feeling anguished, sad, and angry, that last from weeks to months and may occasionally resurface years after the death. There is no one way to grieve, so find the best way for you.
Remember the deceased.	Review your relationship to and experiences with the deceased, permitting yourself to see that you can no longer be with him or her as before. Form a new bond based on memories, keeping it alive through photographs, commemorative donations, prayers, and other symbols and actions.
When ready, invest in new activities and relationships, and master new tasks of daily living.	Identify the roles you must give up and the ones you must assume as a consequence of the death, and take deliberate steps to modify daily life accordingly. Set small goals at first, such as a night at the movies, a dinner date with a friend, a cooking or household repair class, or a week's vacation.

it was okay to keep on living! ... We cheered when one of us accomplished a new task. We also tried to lend a helping hand and heart when we would have one of our bad days! ... This group will always be there for me and I will always be there for them. I love you all! (Lund, 2005)

Follow-up research suggests that group sessions are best suited for fostering loss-oriented coping (confronting and resolving grief), whereas an individually tailored approach works best for restoration-oriented coping (reorganizing daily life) (Lund et al., 2010a). Bereaved adults differ widely in the new roles, relationships, and life skills they need most, and in the formats and schedules best suited to acquiring them.

### LOOK and LISTEN

Arrange to sit in on a bereavement support group session sponsored by a local hospice program or hospital, noting both emotional and daily living challenges expressed by group members. Ask participants to explain how the group has helped them.

Interventions for children and adolescents following violent deaths must protect them from unnecessary reexposure and assist parents and teachers with their own distress so they can effectively offer comfort (Dowd, 2013). In the aftermath of horrific tragedies—such as the mass shootings at Sandy Hook Elementary School in Newtown, Connecticut, in 2012, and at the public health department in San Bernardino, California, in 2015—nurturing and caring relationships with adults are the most powerful way to help children recover from trauma.

A sudden, violent, and unexplainable death; the loss of a child; a death that the mourner feels he or she could have prevented; or an ambivalent or dependent relationship with the deceased makes it harder for bereaved people to overcome their loss. In cases of complicated grief, individual or family therapy with a specially trained professional can be helpful (Stroebe, Schut, & van den Bout, 2013). Assisting bereaved adults in finding some value in the grieving experience—for example, discovering their own capacity to cope with adversity, gaining insight into the meaning of relationships, or crystallizing a sense of purpose in life—is particularly effective (Neimeyer et al., 2010).

Most grieving individuals do not participate in bereavement interventions. In several studies, only 25 to 50 percent of family caregivers of dying patients made use of bereavement services—such as phone support, support groups, and referrals for counseling—even though these were readily available through hospice, hospitals, or other community organizations (Bergman, Haley, & Small, 2011; Ghesquiere, Thomas, & Bruce, 2016). Many who refused services were severely distressed yet did not realize that intervention could be helpful.

## Death Education

**19.7** Explain how death education can help people cope with death more effectively.

Preparatory steps can help people of all ages cope with death more effectively. The death awareness movement that sparked increased sensitivity to the needs of dying patients has also led to

the rise of college and university courses in death, dying, and bereavement. Instruction has been integrated into the training of students or those currently working in the fields of counseling, education, funeral service, nursing, medicine, and ministry, as well as those volunteering in hospice programs. Some institutions offer a major or minor in thanatology, in which students complete a program of courses addressing a variety of death-related subjects (Corr, 2015a). Death education is also found in adult education programs in many communities.

Death education at all levels has the following goals:

- Increasing students' understanding of the physical and psychological changes that accompany dying
- Enhancing students' awareness of options in end-of-life care, funeral services, and memorial rituals
- Promoting understanding of important social and ethical issues, including advance medical directives, medical aid-in-dying, euthanasia, and organ donation
- Improving students' ability to communicate effectively with others about death-related concerns
- Helping to prepare students for their professional roles in caring for the dying and supporting the bereaved
- Fostering students' appreciation of how lifespan development interacts with death, dying, and bereavement issues (Corr & Corr, 2013; Kastenbaum, 2012)

Educational format varies widely. Some programs simply convey information. Others are experiential and include activities such as role-playing, discussions with the terminally ill, visits to mortuaries and cemeteries, and personal awareness exercises. Research reveals that although using a lecture style leads to gains in knowledge, it often leaves students more uncomfortable about

death than when they entered (Hurtig & Stewin, 2006). In contrast, experiential programs that help students confront their own mortality and clarify basic values on living and dying are more likely to have a positive, lasting impact.

Whether acquired in the classroom or in our daily lives, our thoughts and feelings about death are forged through interactions with others. Becoming more aware of how we die and of our own mortality, we encounter our greatest loss, but we also gain. Dying people have at times confided in those close to them that awareness of the limits of their lifespan permitted them to dispense with superficial distractions and wasted energies and focus on what is truly important in their lives. As one terminally ill patient summed up, “[It’s] kind of like life, just speeded up”—an accelerated process in which, over a period of weeks to months, one grapples with issues that normally would have taken years or decades to resolve (Selwyn, 1996, p. 36). Applying this lesson to ourselves, we learn that by being in touch with death and dying, we can live ever more fully.

## Ask yourself

**CONNECT** Compare grieving individuals' reactions with terminally ill patients' thoughts and feelings as they move closer to death, described on page 653. Can a dying person's reactions be viewed as a form of grieving? Explain.

**APPLY** List features of self-help groups that contribute to their effectiveness in helping people cope with loss.

**REFLECT** Visit a Web cemetery, such as Virtual Memorials ([www.virtualmemorials.com](http://www.virtualmemorials.com)). Select examples of Web tributes, guestbook entries, and testimonials that illustrate the unique ways in which virtual cemeteries help people cope with death.

## Summary / chapter 19

### How We Die (p. 646)

**19.1** Describe the physical changes of dying, along with their implications for defining death and the meaning of death with dignity.

- **Thanatology**, the study of death and dying, has expanded dramatically over the past three decades. As a result of life-saving technology, death is long and drawn-out for three-fourths of people—many more than in times past. Of those who die suddenly, 65 to 85 percent are victims of heart attacks.
- In general, dying takes place in three phases: the **agonal phase**, in which regular heartbeat disintegrates; **clinical death**, a short interval in which resuscitation is still possible; and **mortality**, or permanent death.

- In most industrialized nations, **brain death** is accepted as the definition of death. But for incurable patients who remain in a **persistent vegetative state**, the brain death standard does not solve the problem of when to halt treatment.

AP IMAGES/COEUR DALENE PRESS, JEROME A. POLLOS

- We can best ensure death with dignity by supporting dying patients through their physical and psychological distress, being candid about death's certainty, and helping them learn enough about their condition to make reasoned choices about treatment.

### Understanding of and Attitudes Toward Death (p. 648)

**19.2** Discuss age-related changes in conceptions of and attitudes toward death, and cite factors that influence death anxiety.

- Compared with earlier generations, more young people reach adulthood having had little contact with death, contributing to a sense of unease about it.

- To understand death, children must have some basic notions of biology and must be able to distinguish between *dead*, *inanimate*, *unreal*, and *nonexistent*. Most children attain a sophisticated grasp of death by age 6, gradually mastering subconcepts of nonfunctionality, finality, universality, applicability, and causation during the preschool years. Cultural and religious teachings affect children's understanding, as do open, honest discussions.

© RICHARD ELLIS/LAMY

- Adolescents are aware that death happens to everyone and can occur at any time, but their high-risk activities suggest that they do not take death personally. Candid discussions can help teenagers build a bridge between death as a logical possibility and their everyday actions.
- In early adulthood, many people avoid thinking about death, but in midlife, they become more conscious that their own lives are finite. In late adulthood, as death nears, people are more apt to ponder the process of dying than the state of death.
- Wide individual and cultural variations exist in **death anxiety**. People with a sense of spirituality or a well-developed personal philosophy of death are less fearful, as are those with deep faith in a higher force or being. Older adults' greater ability to regulate negative emotion and their sense of symbolic immortality reduce death anxiety. Across cultures, women exhibit more death anxiety than men.

## Thinking and Emotions of Dying People (p. 653)

### 19.3 Describe and evaluate Kübler-Ross's theory of typical responses to dying, and cite factors that influence dying patients' responses.

- Elisabeth Kübler-Ross proposed that dying people typically express five responses: denial, anger, bargaining, depression, and acceptance. These reactions do not occur in fixed sequence, and dying people often display other coping strategies. Still, Kübler-Ross convinced professionals and the general public that the dying are living people who usually have "unfinished needs" they want to address.
- The extent to which people attain an **appropriate death** depends on many contextual variables—nature of the disease, personality and coping style, family members' and health professionals' behavior, and spirituality, religion, and cultural background.

## A Place to Die (p. 657)

### 19.4 Evaluate the extent to which homes, hospitals, nursing homes, and the hospice approach meet the needs of dying people and their families.

- Although most people say they want to die at home, only about one-fourth of Americans do. Even with professional help and hospital-supplied equipment, caring for a dying patient in the home is highly demanding.
- Sudden deaths typically occur in hospital emergency rooms, where sympathetic explanations from staff can reduce family members' anger, frustration, and confusion. Intensive care is especially depersonalizing for patients lingering between life and death while hooked to machines. Although hospital comprehensive treatment programs aimed at easing end-of-life suffering have increased over the past decade, about one-third of hospitals still do not have them.
- Though deaths in U.S. nursing homes are common, too often residents' end-of-life preferences are not followed.
- The **hospice** approach is a comprehensive program of support services that focuses on meeting the dying person's physical, emotional, social, and spiritual needs and providing **palliative**, or **comfort**, **care** rather than prolonging life. Hospice also contributes to improved family functioning and better psychological well-being among family survivors.

## The Right to Die (p. 660)

### 19.5 Discuss end-of-life medical practices, along with ethical controversies surrounding them.

- Modern medical procedures can prolong inevitable death, diminishing quality of life and personal dignity. Ending life-sustaining treatment for terminally ill patients is widely accepted and practiced. People can best ensure that their wishes will be followed by preparing an **advance medical directive**. A **living will** contains instructions for treatment, whereas a **durable power of attorney for health care** names another person to make health-care decisions on one's behalf.

KATARZYNA BIALASIEWICZ/ISTOCK/GETTY IMAGES PLUS

- **Medical aid-in-dying** is legal in five U.S. states, and public and physician support for it has recently increased. Opponents worry that health-care financial pressures or coercion from others might affect patient requests. Because the final act is solely the patient's, many supporters believe that legalizing medical aid-in-dying is preferable to legalizing voluntary euthanasia.
- Although public support for **voluntary euthanasia** is high in North America and Western Europe, the practice remains a criminal offense in most countries and has sparked heated controversy, fueled by fears that it will be applied involuntarily to vulnerable people.

## Bereavement: Coping with the Death of a Loved One (p. 665)

### 19.6 Describe the process of grieving, factors that contribute to individual variations, and bereavement interventions.

- **Bereavement** refers to the experience of losing a loved one by death, **grief** to the intense physical and psychological distress that accompanies loss. **Mourning** is the culturally prescribed expression of the bereaved person's thoughts and feelings.

- Most bereaved individuals recover within a few months to a year. About 5 to 15 percent experience **complicated grief**, severe, prolonged distress, depression, and lack of acceptance of the death.
- The grief process is best conceived as a set of tasks to overcome rather than a series of orderly phases.
- According to the **dual-process model of coping with loss**, effective coping involves oscillating between dealing with the emotional consequences of loss and attending to life changes, which can have restorative effects. Bereaved individuals who experience positive as well as negative emotions cope more effectively.
- Grieving is affected by many personal and situational factors. Bereaved men express grief less directly than bereaved women. After a sudden, unanticipated death, avoidance may be especially pronounced and confrontation highly traumatic. In contrast, a prolonged, expected death allows time for **anticipatory grieving**.

AP IMAGES/MANU BRABO

- When a parent loses a child or a child loses a parent or sibling, grieving is often intense and prolonged. Because early loss of a life partner is a nonnormative event with a major impact on life plans, younger widowed individuals usually fare less well than their older counterparts. **Disenfranchised grief** can profoundly disrupt the grief process.
- People who experience several deaths at once or in close succession may suffer from bereavement overload. Those at risk include aging adults, individuals who have lost loved ones to public tragedies, and people who have witnessed unexpected, violent deaths.

- Sympathy and understanding are sufficient for most people to recover from grief. Support groups are highly effective in aiding recovery, whereas individually tailored approaches help mourners reorganize their daily lives. Interventions for children and adolescents following violent deaths must protect them from unnecessary reexposure and assist parents and teachers in offering comfort.

## Death Education (p. 670)

### 19.7 Explain how death education can help people cope with death more effectively.

- Death education has been integrated into training for students and practitioners in diverse fields and for hospice volunteers. It can also be found in adult education programs. Goals include promoting understanding of end-of-life care options and important social and ethical issues (such as advance medical directives and euthanasia), and of how lifespan development interacts with death, dying, and bereavement.

## Important Terms and Concepts

advance medical directive (p. 661)  
 agonal phase (p. 645)  
 anticipatory grieving (p. 666)  
 appropriate death (p. 654)  
 bereavement (p. 665)  
 brain death (p. 647)  
 clinical death (p. 645)  
 complicated grief (p. 665)

death anxiety (p. 651)  
 disenfranchised grief (p. 668)  
 dual-process model of coping with loss (p. 665)  
 durable power of attorney for health care (p. 662)  
 grief (p. 665)  
 hospice (p. 658)  
 living will (p. 661)  
 medical aid-in-dying (p. 662)

mortality (p. 645)  
 mourning (p. 665)  
 palliative, or comfort, care (p. 658)  
 persistent vegetative state (p. 647)  
 thanatology (p. 645)  
 voluntary euthanasia (p. 664)

# Glossary

## A

**academic programs** Preschool and kindergarten programs in which teachers structure children's learning, teaching academic skills through formal lessons that often involve repetition and drill. Distinguished from *child-centered programs*. (p. 246)

**accommodation** In Piaget's theory, the part of adaptation in which new schemes are created and old ones adjusted to produce a better fit with the environment. Distinguished from *assimilation*. (p. 150)

**acculturative stress** Psychological distress resulting from conflict between an individual's minority culture and the host culture. (p. 412)

**activities of daily living (ADLs)** Basic self-care tasks required to live on one's own, such as bathing, dressing, getting in and out of bed or a chair, and eating. (p. 573)

**adaptation** In Piaget's theory, the process of building schemes through direct interaction with the environment. Consists of two complementary activities: *assimilation* and *accommodation*. (p. 150)

**adolescence** The transition between childhood and adulthood that begins with puberty. It involves accepting one's full-grown body, acquiring adult ways of thinking, attaining greater independence from one's family, developing more mature ways of relating to peers of both sexes, and beginning to construct an identity. (p. 367)

**advance medical directive** A written statement of desired medical treatment should a person become incurably ill. (p. 661)

**age-graded influences** Influences on lifespan development that are strongly related to age and therefore fairly predictable in when they occur and how long they last. (p. 9)

**age of viability** The point at which the baby can first survive if born early, occurring sometime between 22 and 26 weeks. (p. 80)

**aging in place** In late adulthood, remaining in a familiar setting where one has control over one's everyday life. (p. 623)

**agonal phase** The phase of dying characterized by a rattled breathing sound, due to fluid buildup in the throat, and by gasps and muscle spasms during the first moments in which the regular heartbeat disintegrates. Distinguished from *clinical death* and *mortality*. (p. 645)

**alcohol-related neurodevelopmental disorder (ARND)** The least severe form of fetal alcohol spectrum disorder, involving brain injury but with typical physical growth and absence of facial abnormalities. Distinguished from *fetal alcohol syndrome (FAS)* and *partial fetal alcohol syndrome (p-FAS)*. (p. 84)

**allele** Each of two forms of a gene located at the same place on corresponding pairs of chromosomes. (p. 46)

**Alzheimer's disease** The most common form of dementia, in which structural and chemical brain deterioration is associated with gradual loss of many aspects of thought and behavior, including memory, skilled and purposeful movements, and comprehension and production of speech. (p. 588)

**amnion** The inner membrane that encloses the developing organism in *amniotic fluid*, which helps keep the temperature of the prenatal world constant and provides a cushion against jolts caused by the woman's movements. (p. 77)

**amygdala** An inner-brain structure that plays a central role in processing of novelty and emotional information. (p. 218)

**amyloid plaques** A structural change in the cerebral cortex associated with Alzheimer's disease, in which dense deposits of a deteriorated protein called *amyloid* develop, surrounded by clumps of dead nerve and glial cells. (p. 588)

**androgyny** The gender identity held by individuals who score high on both traditionally masculine and traditionally feminine personality characteristics. (p. 279)

**anorexia nervosa** An eating disorder in which young people, mainly females, starve themselves because of a compulsive fear of getting fat and an extremely distorted body image. (p. 378)

**anoxia** Inadequate oxygen supply. (p. 96)

**anticipatory grieving** During prolonged dying, the bereaved person's acknowledgment that the loss is inevitable, and emotional preparation for it. (p. 666)

**Apgar Scale** A rating system used to assess a newborn baby's physical condition immediately after birth on the basis of five characteristics: heart rate, respiratory effort, reflex irritability, muscle tone, and color. (p. 94)

**applied behavior analysis** Careful observations of individual behavior and related environmental events, followed by systematic changes in those events based on procedures of conditioning and modeling. The goal is to eliminate undesirable behaviors and increase desirable responses. (p. 17)

**appropriate death** A death that makes sense in terms of the individual's pattern of living and values, preserves or restores significant relationships, and is as free of suffering as possible. (p. 654)

**assimilation** In Piaget's theory, the part of adaptation in which current schemes are used to interpret the external world. Distinguished from *accommodation*. (p. 150)

**assisted living** Homelike housing arrangements for older adults who require more help than can be provided at home but less than is usually provided in nursing homes. (p. 593)

**assistive technology** An array of devices that permit people with disabilities, including older adults, to improve their functioning. (p. 579)

**associative memory deficit** Age-related difficulty creating and retrieving links between pieces of information—for example, two items or an item and its context. (p. 596)

**associative play** A form of social interaction in which children engage in separate activities but exchange toys and comment on one another's behavior. Distinguished from *nonsocial activity*, *parallel play*, and *cooperative play*. (p. 263)

**attachment** The strong affectionate tie we have with special people in our lives, which leads us to feel pleasure when interacting with them and to be comforted by their nearness in times of stress. (p. 196)

**Attachment Q-Sort** A method for assessing the quality of attachment in children between 1 and 5 years of age through home observations of a variety of attachment-related behaviors. (p. 198)

**attention-deficit hyperactivity disorder (ADHD)** A childhood disorder involving inattention, impulsivity, and excessive motor activity, resulting in academic and social problems. (p. 309)

**authoritarian child-rearing style** A child-rearing style that is low in acceptance and involvement, high in coercive and psychological control, and low in autonomy granting. Distinguished from *authoritative*, *permissive*, and *uninvolved child-rearing styles*. (p. 283)

**authoritative child-rearing style** A child-rearing style that is high in acceptance and involvement, adaptive control techniques, and appropriate autonomy granting. Distinguished from *authoritarian*, *permissive*, and *uninvolved child-rearing styles*. (p. 282)

**autobiographical memory** Long-lasting recollections of personally meaningful one-time events from both the recent and the distant past. (p. 164)

**autoimmune response** A malfunction of the immune system in which it turns against normal body tissues. (p. 577)

**automatic processes** Cognitive activities that are so well-learned that they require no space in working memory and, therefore, permit an individual to focus on other information while performing them. (p. 161)

**autonomy** At adolescence, a sense of oneself as a separate, self-governing individual. Involves relying more on oneself and less on parents for support and guidance and engaging in careful, well-reasoned decision making. (p. 420)

**autonomy versus shame and doubt** In Erikson's theory, the psychological conflict of toddlerhood, which is resolved favorably when parents provide young children with suitable guidance and reasonable choices. (p. 184)

**autosomes** The 22 matching pairs of chromosomes in each human cell. (p. 45)

**average healthy life expectancy** The number of years that an individual born in a particular year can expect to live in full health, without disease or injury. Distinguished from *maximum lifespan* and *average life expectancy*. (p. 571)

**average life expectancy** The number of years that an individual born in a particular year can expect to live, starting at any age. Distinguished from *maximum lifespan* and *average healthy life expectancy*. (p. 570)

**B**

- babbling** Infants' repetition of consonant–vowel combinations, beginning around 6 months of age. (p. 175)
- basal metabolic rate (BMR)** The amount of energy the body uses at complete rest. (p. 446)
- basic emotions** Emotions such as happiness, interest, surprise, fear, anger, sadness, and disgust that are universal in humans and other primates and have a long evolutionary history of promoting survival. (p. 185)
- basic trust versus mistrust** In Erikson's theory, the psychological conflict of infancy, which is resolved positively when the balance of care is sympathetic and loving. (p. 184)
- behavioral genetics** A field devoted to uncovering the contributions of nature and nurture to the diversity of human traits and abilities. (p. 66)
- behaviorism** An approach that regards directly observable events—stimuli and responses—as the appropriate focus of study and views the development of behavior as taking place through classical and operant conditioning. (p. 16)
- bereavement** The experience of losing a loved one by death. (p. 665)
- bicultural identity** The identity constructed by exploring and adopting values from both the individual's subculture and the dominant culture. (p. 412)
- “big five” personality traits** Five basic factors into which hundreds of personality traits have been organized: neuroticism, extroversion, openness to experience, agreeableness, and conscientiousness. (p. 548)
- biological aging, or senescence** Genetically influenced, age-related declines in the functioning of organs and systems that are universal in all members of our species. Sometimes called *primary aging*. (p. 438)
- binge-eating disorder** An eating disorder in which young people binge at least once a week for three months or longer, without compensatory purging, exercise, or fasting. (p. 379)
- blended, or reconstituted, family** A family structure resulting from remarriage or cohabitation that includes parent, child, and steprelatives. (p. 356)
- body image** Conception of and attitude toward one's physical appearance. (p. 377)
- brain death** Irreversible cessation of all activity in the brain and the brain stem. The definition of death accepted in most industrialized nations. (p. 647)
- brain plasticity** The capacity of various parts of the cerebral cortex to take over functions of damaged regions. Declines as hemispheres of the cerebral cortex lateralize. (p. 121)
- breech position** A position of the baby in the uterus that would cause the buttocks or feet to be delivered first. (p. 96)
- bulimia nervosa** An eating disorder in which individuals, mainly females, engage in binge eating, followed by compensatory efforts to avoid weight gain, such as deliberate vomiting, purging with laxatives, excessive exercise, or fasting. (p. 379)
- burnout** A condition in which long-term job stress leads to mental exhaustion, a sense of loss of personal control, and feelings of reduced accomplishment. (p. 560)

**C**

- cardinality** The mathematical principle specifying that the last number in a counting sequence indicates the quantity of items in the set. (p. 244)
- carriers** Heterozygous individuals who can pass a recessive trait to their offspring. (p. 46)
- cataracts** Cloudy areas in the lens of the eye that increase from middle to late adulthood, resulting in foggy vision and (without surgery) eventual blindness. (p. 574)
- categorical self** Classification of the self on the basis of prominent ways in which people differ, such as age, sex, physical characteristics, goodness versus badness, and competencies. Develops between 18 and 30 months. (p. 208)
- central executive** In information processing, the conscious, reflective part of our mental system that directs the flow of information, coordinating incoming information with information already in the system and selecting, applying, and monitoring strategies that facilitate memory storage, comprehension, reasoning, and problem solving. (p. 161)
- centration** In Piaget's theory, the tendency of preoperational children to focus on one aspect of a situation while neglecting other important features. (p. 230)
- cephalocaudal trend** An organized pattern of physical growth that proceeds from the upper to the lower part of the body (“head to tail”). Distinguished from *proximodistal trend*. (p. 117)
- cerebellum** A structure at the rear and base of the brain that aids in balance and control of body movement. (p. 218)
- cerebral cortex** The largest, most complex structure of the human brain, which contains the greatest number of neurons and synapses and accounts for the highly developed intelligence of the human species. (p. 120)
- cesarean delivery** A surgical birth, in which the doctor makes an incision in the mother's abdomen and lifts the baby out of the uterus. (p. 97)
- child-centered programs** Preschool and kindergarten programs in which teachers provide a variety of activities from which children select, and much learning takes place through play. Distinguished from *academic programs*. (p. 246)
- child-rearing styles** Combinations of parenting behaviors that occur over a wide range of situations, creating an enduring child-rearing climate. (p. 282)
- chorion** The outer membrane that surrounds the amnion, forming a protective covering around the developing organism. It sends out tiny fingerlike *villi*, from which the placenta begins to develop. (p. 78)
- chromosomes** Rodlike structures in the cell nucleus that store and transmit genetic information. (p. 44)
- chronosystem** In ecological systems theory, the temporal dimension of the environment, in which life changes can either be imposed externally or, alternatively, can arise from within the person. Distinguished from *microsystem*, *mesosystem*, *exosystem*, and *macrosystem*. (p. 26)
- circular reaction** In Piaget's theory, a means of building schemes in which infants try to repeat a chance event caused by their own motor activity. (p. 151)
- classical conditioning** A form of learning that involves associating a neutral stimulus with a stimulus that leads to a reflexive response. Once the nervous system makes the connection between the two stimuli, the neutral stimulus alone produces the behavior. (p. 130)
- climacteric** The midlife transition in which fertility declines, bringing an end to reproductive capacity in women and diminished fertility in men. (p. 510)
- clinical death** The phase of dying in which heartbeat, circulation, breathing, and brain functioning stop, but resuscitation is still possible. Distinguished from *agonal phase* and *mortality*. (p. 645)
- clinical interview** An interview method in which the researcher uses a flexible, conversational style to probe for the participant's point of view. Distinguished from *structured interview*. (p. 29)
- clinical, or case study, method** A research method in which the aim is to obtain as complete a picture as possible of one individual's psychological functioning and the experiences that led up to it by bringing together interview data, observations, and test scores. (p. 30)
- clique** A group of about five to seven members who are friends and, therefore, usually resemble one another in family background, attitudes, values, and interests. (p. 425)
- cognitive-affective complexity** In Labouvie-Vief's theory, a form of thinking that increases from adolescence through middle adulthood, involving awareness of conflicting positive and negative feelings and coordination of them into a complex, organized structure that recognizes the uniqueness of individual experiences. (p. 458)
- cognitive-developmental theory** Piaget's view that children actively construct knowledge as they manipulate and explore their world and that cognitive development takes place in stages. (p. 17)
- cognitive maps** Mental representations of familiar spaces, such as a classroom, school, or neighborhood. (p. 304)
- cognitive reserve** Reorganization of brain areas devoted to cognitive processes and richer synaptic connections, resulting from the complex cognitive activities of better-educated people, which give the aging brain greater tolerance for injury before it crosses the threshold into mental disability. (p. 590)
- cognitive self-regulation** The process of continuously monitoring progress toward a goal, checking outcomes, and redirecting unsuccessful efforts. (p. 312)
- cohabitation** The lifestyle of unmarried couples who have a sexually intimate relationship and who share a residence. (p. 494)

- cohort effects** The effects of cultural–historical change on the accuracy of longitudinal and cross-sectional research findings. Results based on one cohort—individuals developing in the same time period, who are influenced by particular historical and cultural conditions—may not apply to other cohorts. (p. 35)
- commitment within relativistic thinking** In Perry’s theory, the mature individual’s formulation of a perspective that synthesizes contradictions between opposing views, rather than choosing between them. (p. 457)
- companionate love** Love based on warm, trusting affection and valuing of the other. Distinguished from *passionate love* and *compassionate love*. (p. 479)
- compassionate love** Love based on concern for the other’s well-being, expressed through caring efforts to alleviate the other’s distress and promote the other’s growth and flourishing. (p. 479)
- compliance** Voluntary obedience to requests and commands. (p. 209)
- complicated grief** A bereaved person’s severe, prolonged distress, depression, and lack of acceptance of the death that persists for years, impairing physical and mental health. (p. 665)
- compression of morbidity** The public health goal of reducing the average period of diminished vigor before death as life expectancy extends. Medical advances and improved socioeconomic conditions promote this goal. (p. 582)
- concrete operational stage** Piaget’s third stage of cognitive development, extending from about 7 to 11 years, during which thought becomes logical, flexible, and organized in its application to concrete information, but the capacity for abstract thinking is not yet present. (p. 304)
- conditioned response (CR)** In classical conditioning, a new response elicited by a conditioned stimulus (CS) that is similar to the unconditioned, or reflexive, response (UCR). (p. 131)
- conditioned stimulus (CS)** In classical conditioning, a neutral stimulus that, through pairing with an unconditioned stimulus (UCS), leads to a new, conditioned response. (CR). (p. 131)
- conservation** The understanding that certain physical characteristics of objects remain the same, even when their outward appearance changes. (p. 229)
- constructivist classroom** A classroom grounded in Piaget’s view of children as active agents who construct their own knowledge. Features include richly equipped learning centers, small groups and individuals solving self-chosen problems, a teacher who guides and supports in response to children’s needs, and evaluation based on individual students’ progress in relation to their own prior development. Distinguished from *traditional* and *social-constructivist classrooms*. (p. 324)
- contexts** Unique combinations of personal and environmental circumstances that can result in different paths of development. (p. 6)
- continuity theory** A social theory of aging that states that most aging adults, in their choice of everyday activities and social relationships, strive to maintain a personal system—an identity and a set of personality dispositions, interests, roles, and skills—that promotes life satisfaction by ensuring consistency between their past and anticipated future. (p. 620)
- continuous development** The view that development is a process of gradually augmenting the same types of skills that were there to begin with. Distinguished from *discontinuous development*. (p. 6)
- contrast sensitivity** A general principle accounting for early pattern preferences, which states that if babies can detect the contrast in two or more patterns, they prefer the pattern with more contrast. (p. 141)
- controversial children** Children who receive many votes, both positive and negative, on self-report measures of peer acceptance, indicating that they are both liked and disliked. Distinguished from *popular*, *neglected*, and *rejected children*. (p. 347)
- conventional level** Kohlberg’s second level of moral development, in which moral understanding is based on conformity to social rules to ensure positive human relationships and maintain societal order. (p. 414)
- convergent thinking** The type of cognition emphasized on intelligence tests, which involves arriving at a single correct answer to a problem. Distinguished from *divergent thinking*. (p. 328)
- cooing** Pleasant vowel-like noises made by infants beginning around 2 months of age. (p. 175)
- cooperative learning** Collaboration on a task by a small group of classmates who work toward common goals by considering one another’s ideas, appropriately challenging one another, providing sufficient explanations to correct misunderstandings, and resolving differences of opinion on the basis of reasons and evidence. (p. 325)
- cooperative play** A form of social interaction in which children orient toward a common goal, such as acting out a make-believe theme. Distinguished from *nonsocial activity*, *parallel play*, and *associative play*. (p. 263)
- coparenting** Parents’ mutual support of each other’s parenting behaviors. (p. 57)
- coregulation** A form of supervision in which parents exercise general oversight while letting children take charge of moment-by-moment decision making. (p. 352)
- core knowledge perspective** A perspective that states that infants are born with a set of innate knowledge systems, or core domains of thought, each of which permits a ready grasp of new, related information and therefore supports early, rapid development of certain aspects of cognition. (p. 158)
- corpus callosum** The large bundle of fibers connecting the two hemispheres of the cerebral cortex. Supports smooth coordination of movements on both sides of the body and integration of many aspects of thinking. (p. 219)
- correlational design** A research design in which investigators gather information on individuals without altering their experiences and then examine relationships between participants’ characteristics and their behavior or development. Does not permit inferences about cause and effect. (p. 31)
- correlation coefficient** A number, ranging from +1.00 to –1.00, that describes the strength and direction of the relationship between two variables. (p. 33)
- creativity** The ability to produce work that is *original yet appropriate*—something others have not thought of that is useful in some way. (p. 328)
- cross-linkage theory of aging** A theory of biological aging asserting that the formation of bonds, or links, between normally separate protein fibers causes the body’s connective tissue to become less elastic over time, leading to many negative physical outcomes. (p. 440)
- cross-sectional design** A research design in which groups of participants differing in age are studied at the same point in time. Distinguished from *longitudinal design*. (p. 36)
- crowd** A large, loosely organized social group consisting of several cliques with similar values. Membership is based on reputation and stereotype. (p. 425)
- crystallized intelligence** Intellectual skills that depend on accumulated knowledge and experience, good judgment, and mastery of social conventions—abilities acquired because they are valued by the individual’s culture. Distinguished from *fluid intelligence*. (p. 525)
- D**
- death anxiety** Fear and apprehension of death. (p. 651)
- deferred imitation** The ability to remember and copy the behavior of models who are not present. (p. 153)
- delay of gratification** The ability to wait for an appropriate time and place to engage in a tempting act. (p. 209)
- dementia** A set of disorders occurring almost entirely in old age in which many aspects of thought and behavior are so impaired that everyday activities are disrupted. (p. 587)
- deoxyribonucleic acid (DNA)** Long, double-stranded molecules that make up chromosomes. (p. 44)
- dependency–support script** A predictable pattern of interaction in which caregivers attend to older adults’ dependent behaviors immediately, thereby reinforcing those behaviors, while ignoring independent behaviors. Distinguished from *independence–ignore script*. (p. 616)
- dependent variable** The variable the researcher expects to be influenced by the independent variable in an experiment. Distinguished from *independent variable*. (p. 33)
- developmental cognitive neuroscience** An area of investigation that brings together researchers from psychology, biology, neuroscience, and medicine to study the relationship between changes in the brain and the developing person’s cognitive processing and behavior patterns. (p. 20)
- developmentally appropriate practice** A set of standards devised by the U.S. National Association for the Education of Young Children, specifying program characteristics that serve young children’s developmental and individual needs, based on current research and consensus among experts. (p. 171)

- developmental quotient (DQ)** A score on an infant intelligence test, computed in the same manner as an IQ but labeled more conservatively because it does not tap the same dimensions of intelligence assessed in older children. (p. 169)
- developmental science** An interdisciplinary field devoted to understanding constancy and change throughout the lifespan. (p. 5)
- developmental social neuroscience** A new field devoted to studying the relationship between changes in the brain and emotional and social development. (p. 20)
- differentiation theory** The view that perceptual development involves the detection of increasingly fine-grained, invariant features in the environment. (p. 144)
- difficult child** A child whose temperament is characterized by irregularity in daily routines, slowness in accepting new experiences, and a tendency to react negatively and intensely. Distinguished from *easy child* and *slow-to-warm-up child*. (p. 190)
- discontinuous development** The view that development is a process in which new ways of understanding and responding to the world emerge at specific times. Distinguished from *continuous development*. (p. 6)
- disenfranchised grief** A sense of loss without the opportunity to mourn publicly and benefit from others' support. (p. 668)
- disorganized/disoriented attachment** The attachment pattern reflecting the greatest insecurity, characterizing infants who show confused, contradictory responses when reunited with the parent after a separation. Distinguished from *secure*, *avoidant*, and *resistant attachment*. (p. 198)
- displaced reference** The realization that words can be used to cue mental images of things that are not physically present. (p. 156)
- divergent thinking** The type of thinking associated with creativity, which involves generating multiple and unusual possibilities when faced with a task or problem. Distinguished from *convergent thinking*. (p. 328)
- dominance hierarchy** A stable ordering of group members that predicts who will win when conflict arises. (p. 302)
- dominant cerebral hemisphere** The hemisphere of the cerebral cortex responsible for skilled motor action and other important abilities. In right-handed individuals, the left hemisphere is dominant; in left-handed individuals, motor and language skills are often shared between the hemispheres. (p. 218)
- dominant–recessive inheritance** A pattern of inheritance in which, under heterozygous conditions, only one allele, called *dominant*, affects the child's characteristics. The second allele, which has no effect, is called *recessive*. (p. 46)
- dualistic thinking** In Perry's theory, the cognitive approach typical of younger college students, who divide information, values, and authority into right and wrong, good and bad, we and they. Distinguished from *relativistic thinking*. (p. 456)
- dual-process model of coping with loss** A perspective that assumes that effective coping requires bereaved people to oscillate between dealing with the emotional consequences of loss and attending to life changes, which—when handled successfully—have restorative, or healing, effects. (p. 665)
- dual representation** The ability to view a symbolic object as both an object in its own right and a symbol. (p. 229)
- durable power of attorney for health care** A written statement authorizing appointment of another person (usually, though not always, a family member) to make health-care decisions on one's behalf. (p. 662)
- dynamic assessment** An approach to testing consistent with Vygotsky's zone of proximal development, in which purposeful teaching is introduced into the testing situation to find out what the child can attain with social support. (p. 320)
- dynamic systems theory of motor development** A theory that views mastery of motor skills as a process of acquiring increasingly complex *systems of action*, in which separate abilities blend together, each cooperating with others to produce more effective ways of exploring and controlling the environment. Each new skill is a joint product of central nervous system development, the body's movement capacities, the child's goals, and environmental supports for the skill. (p. 135)
- tation to new experiences.** Distinguished from *difficult child* and *slow-to-warm-up child*. (p. 190)
- ecological systems theory** Bronfenbrenner's approach, which views the person as developing within a complex system of relationships affected by multiple levels of the surrounding environment, from immediate settings of family and school to broad cultural values and programs. (p. 23)
- educational self-fulfilling prophecies** Teachers' positive or negative views of individual children, who tend to adopt and start to live up to those views. (p. 326)
- effortful control** The self-regulatory dimension of temperament, involving the capacity to voluntarily suppress a dominant response in order to plan and execute a more adaptive response. (p. 191)
- egalitarian marriage** A form of marriage in which partners relate as equals, sharing power and authority. Both try to balance the time and energy they devote to their occupations, their children, and their relationship. Distinguished from *traditional marriage*. (p. 486)
- egocentrism** Failure to distinguish others' symbolic viewpoints from one's own. (p. 229)
- ego integrity versus despair** In Erikson's theory, the psychological conflict of late adulthood, which is resolved positively when older adults come to terms with their lives and feel whole, complete, and satisfied with their achievements. (p. 610)
- elaboration** A memory strategy that involves creating a relationship, or shared meaning, between two or more pieces of information that do not belong to the same category. (p. 310)
- embryo** The prenatal organism from 2 to 8 weeks after conception—the period when the groundwork is laid for all body structures and internal organs. (p. 78)
- emergent literacy** Children's active efforts to construct literacy knowledge through informal experiences. (p. 242)
- emerging adulthood** A new transitional period of development, extending from the late teens to the mid- to late twenties, during which young people have left adolescence but have not yet assumed adult responsibilities. Rather, they explore alternatives in education, work, and personal values and behavior more intensely than they did in adolescence. (p. 470)
- emotional self-regulation** Strategies for adjusting our emotional state to a comfortable level of intensity so we can accomplish our goals. (p. 189)
- emotion-centered coping** A strategy for managing emotion that is internal, private, and aimed at controlling distress when little can be done about an outcome. Distinguished from *problem-centered coping*. (p. 342)
- empathy** The ability to understand another's emotional state and *feel with* that person, or respond emotionally in a similar way. (p. 208)
- epigenesis** Development resulting from ongoing, bidirectional exchanges between heredity and all levels of the environment. (p. 70)
- episodic memory** Memory for everyday experiences. Distinguished from *semantic memory*. (p. 240)
- epistemic cognition** Reflections on how one arrived at facts, beliefs, and ideas. (p. 456)
- ethnic identity** A sense of ethnic group membership and the attitudes, beliefs, and feelings associated with that membership, as an enduring aspect of the self. (p. 412)
- ethnography** A research method in which the researcher attempts to understand a culture or a distinct social group through *participant observation*—living with its members and gathering field notes over an extended period of time. (p. 30)
- ethological theory of attachment** Bowlby's theory, the most widely accepted view of attachment, which recognizes the infant's emotional tie to the caregiver as an evolved response that promotes survival. (p. 196)
- ethology** An approach concerned with the adaptive, or survival, value of behavior and its evolutionary history. (p. 21)
- evolutionary developmental psychology** An area of research that seeks to understand the adaptive value of species-wide cognitive, emotional, and social competencies as those competencies change with age. (p. 22)
- executive function** In information processing, the diverse cognitive operations and strategies that enable us to achieve our goals in cognitively challenging situations. These include controlling attention by inhibiting impulses and irrelevant actions and by flexibly directing thought and behavior to suit the demands of a task; coordinating information in working memory; and planning. (p. 161)
- E**
- easy child** A child whose temperament is characterized by quick establishment of regular routines in infancy, general cheerfulness, and easy adap-

**exosystem** In ecological systems theory, the level of the environment consisting of social settings that do not contain the developing person but nevertheless affect experiences in immediate settings. Distinguished from *microsystem*, *mesosystem*, *macrosystem*, and *chronosystem*. (p. 24)

**expansions** Adult responses that elaborate on children's speech, increasing its complexity. (p. 252)

**experience-dependent brain growth** Growth and refinement of established brain structures as a result of specific learning experiences that vary widely across individuals and cultures. Distinguished from *experience-expectant brain growth*. (p. 124)

**experience-expectant brain growth** The young brain's rapidly developing organization, which depends on ordinary experiences—opportunities to explore the environment, interact with people, and hear language and other sounds. Distinguished from *experience-dependent brain growth*. (p. 124)

**experimental design** A research design in which investigators randomly assign participants to two or more treatment conditions and then study the effect that manipulating an independent variable has on a dependent variable. Permits inferences about cause and effect. (p. 33)

**expertise** Acquisition of extensive knowledge in a field or endeavor. (p. 458)

**explicit memory** Memory that requires controlled, strategic processing. Distinguished from *implicit memory*. (p. 596)

**expressive style of language learning** A style of early language learning in which toddlers use language mainly to talk about their own and others' feelings and needs, with an initial vocabulary emphasizing social formulas and pronouns. Distinguished from *referential style of language learning*. (p. 178)

**extended-family households** Households in which parent and child live with one or more adult relatives. (p. 62)

## F

**family life cycle** A series of phases characterizing the development of most families around the world. In early adulthood, people typically live on their own, marry, and bear and rear children. In middle age, parenting responsibilities diminish. Late adulthood brings retirement, growing old, and (more often for women) death of one's spouse. (p. 484)

**fantasy period** Period of vocational development in which children gain insight into career options by fantasizing about them. Distinguished from *tentative period* and *realistic period*. (p. 462)

**fast-mapping** Children's ability to connect new words with their underlying concepts after only a brief encounter. (p. 250)

**feminization of poverty** A trend in which women who support themselves or their families have become the majority of the adult population living in poverty, regardless of age and ethnic group. (p. 550)

**fetal alcohol spectrum disorder (FASD)** A range of physical, mental, and behavioral outcomes caused by prenatal alcohol exposure, including *fetal alcohol syndrome (FAS)*, *partial fetal alcohol syndrome (p-FAS)*, and *alcohol-related neurodevelopmental disorder (ARND)*. (p. 84)

**fetal alcohol syndrome (FAS)** The most severe form of fetal alcohol spectrum disorder, distinguished by slow physical growth, facial abnormalities, and brain injury. Usually affects children whose mothers drank heavily throughout pregnancy. Distinguished from *partial fetal alcohol syndrome (p-FAS)* and *alcohol-related neurodevelopmental disorder (ARND)*. (p. 84)

**fetal monitors** Electronic instruments that track the baby's heart rate during labor. (p. 96)

**fetus** The developing organism from the ninth week to the end of pregnancy—the period during which body structures are completed and dramatic growth in size occurs. (p. 79)

**fluid intelligence** Intellectual skills that largely depend on basic information-processing skills—ability to detect relationships among visual stimuli, speed of analyzing information, and capacity of working memory. Influenced less by culture than by conditions in the brain and by learning unique to the individual. Distinguished from *crystallized intelligence*. (p. 525)

**Flynn effect** The steady increase in IQ from one generation to the next. (p. 319)

**formal operational stage** Piaget's highest stage of cognitive development, beginning around age 11, in which young people develop the capacity for abstract, systematic, scientific thinking. (p. 388)

**frailty** Weakened functioning of diverse organs and body systems, which profoundly interferes with everyday competence and leaves older adults highly vulnerable in the face of infection, extremely hot or cold weather, or injury. (p. 585)

**fraternal, or dizygotic, twins** Twins resulting from the release and fertilization of two ova. They are genetically no more alike than ordinary siblings. Distinguished from *identical*, or *monozygotic, twins*. (p. 45)

**free radicals** Naturally occurring, highly reactive chemicals that form in the presence of oxygen within cells and, at toxic levels, cause DNA and cellular damage, increasing vulnerability to wide-ranging disorders of aging. (p. 440)

**functional age** Actual competence and performance of an older adult, as distinguished from chronological age. (p. 570)

## G

**gametes** The sex cells, or sperm and ovum, which contain half as many chromosomes as regular body cells. (p. 44)

**gender constancy** A full understanding of the biologically based permanence of one's gender, including the realization that sex remains the same even if clothing, hairstyle, and play activities change. (p. 279)

**gender identity** An image of oneself as relatively masculine or feminine in characteristics. (p. 279)

**gender schema theory** An information-processing approach to gender typing that combines social learning and cognitive-developmental features to explain how environmental pressures and children's cognitions work together to shape gender-role development. (p. 279)

**gender typing** Any association of objects, roles, or traits with one sex or the other in ways that conform to cultural stereotypes. (p. 276)

**gene** A segment of DNA along the length of the chromosome containing instructions for making proteins that contribute to body growth and functioning. (p. 44)

**gene-environment correlation** The idea that individuals' genes influence the environments to which they are exposed. (p. 68)

**gene-environment interaction** The view that because of their genetic makeup, individuals differ in their responsiveness to qualities of the environment. (p. 68)

**generativity versus stagnation** In Erikson's theory, the psychological conflict of midlife, which is resolved positively if the adult can integrate personal goals with the welfare of the larger social world. The resulting strength is the capacity to give to and guide the next generation. (p. 538)

**genetic counseling** A communication process designed to help couples assess their chances of giving birth to a baby with a hereditary disorder and choose the best course of action in view of risks and family goals. (p. 51)

**genomic imprinting** A pattern of inheritance in which alleles are imprinted, or chemically marked, in such a way that one pair member is activated, regardless of its makeup. (p. 49)

**genotype** An individual's genetic makeup. Distinguished from *phenotype*. (p. 43)

**gerotranscendence** According to Joan Erikson, a psychosocial stage representing development beyond ego integrity, characterized by a cosmic and transcendent perspective directed beyond the self to affinity with past and future generations and oneness with the universe. (p. 611)

**gifted** Displaying exceptional intellectual strengths, such as high IQ, high potential for creativity, or specialized talent. (p. 328)

**glass ceiling** Invisible barrier to advancement up the corporate ladder, faced by women and ethnic minorities. (p. 561)

**glaucoma** A disease in which poor fluid drainage leads to a buildup of pressure within the eye, damaging the optic nerve. A leading cause of blindness among older adults. (p. 509)

**glial cells** Cells that are responsible for myelination of neural fibers, which improves the efficiency of message transfer. (p. 118)

**goodness-of-fit model** A model proposed by Thomas and Chess to explain how favorable adjustment depends on an effective match, or good fit, between a child's temperament and the child-rearing environment. (p. 195)

**grief** Intense physical and psychological distress following the death of a loved one. (p. 665)

**growth hormone (GH)** A pituitary hormone that affects the development of almost all body tissues. (p. 219)

**growth spurt** Rapid gain in height and weight that is the first outward sign of puberty. (p. 369)

**guided participation** Shared endeavors between more expert and less expert participants, without specifying the precise features of communication, thereby allowing for variations across situations and cultures. A broader concept than *scaffolding*. (p. 236)

## H

**habituation** A gradual reduction in the strength of a response due to repetitive stimulation. (p. 131)

**hardiness** A set of three personal qualities—control, commitment, and challenge—that, together, help people cope adaptively with stress brought on by inevitable life changes. (p. 522)

**heritability estimate** A statistic that measures the extent to which individual differences in complex traits, such as intelligence or personality, in a specific population are due to genetic factors. (p. 67)

**heterozygous** Having two different alleles at the same place on a pair of chromosomes. Distinguished from *homozygous*. (p. 46)

**hierarchical classification** The organization of objects into classes and subclasses on the basis of similarities and differences. (p. 230)

**hippocampus** An inner-brain structure that plays a vital role in memory and in images of space that help us find our way. (p. 218)

**history-graded influences** Influences on lifespan development that are unique to a particular historical era and explain why people born around the same time (called a *cohort*) tend to be alike in ways that set them apart from people born at other times. (p. 9)

**Home Observation for Measurement of the Environment (HOME)** A checklist for gathering information about the quality of children's home lives through observation and parental interview. (p. 170)

**homozygous** Having two identical alleles at the same place on a pair of chromosomes. Distinguished from *heterozygous*. (p. 46)

**hormone therapy** Low daily doses of estrogen, either alone or in combination with progesterone, aimed at reducing the physical discomforts of menopause. (p. 512)

**hospice** A comprehensive program of support services for terminally ill people and their families, which regards the patient and family as a unit of care and emphasizes meeting the patient's physical, emotional, social, and spiritual needs while also providing follow-up bereavement services to the family. (p. 658)

**hypothetico-deductive reasoning** A formal operational problem-solving strategy in which adolescents begin with a *hypothesis*, or prediction about variables that might affect an outcome, from which they deduce logical, testable inferences. Then they systematically isolate and combine variables to see which of those inferences are confirmed in the real world. (p. 388)

## I

**identical, or monozygotic, twins** Twins that result when a zygote that has started to duplicate separates into two clusters of cells with the same genetic makeup, which develop into two individuals. Distinguished from *fraternal, or dizygotic, twins*. (p. 46)

**identity** A well-organized conception of the self that defines who one is, what one values, and what directions one chooses to pursue in life. (p. 408)

**identity achievement** The identity status of individuals who, after a period of exploration, have committed themselves to a clearly formulated set of self-chosen values and goals. Distinguished from *identity moratorium, identity foreclosure, and identity diffusion*. (p. 408)

**identity diffusion** The identity status of individuals who do not engage in exploration and are not committed to values and goals. Distinguished from *identity achievement, identity moratorium, and identity foreclosure*. (p. 408)

**identity foreclosure** The identity status of individuals who do not engage in exploration but, instead, are committed to ready-made values and goals chosen for them by authority figures. Distinguished from *identity achievement, identity moratorium, and identity diffusion*. (p. 408)

**identity moratorium** The identity status of individuals who are exploring but not yet committed to self-chosen values and goals. Distinguished from *identity achievement, identity foreclosure, and identity diffusion*. (p. 408)

**identity versus role confusion** In Erikson's theory, the psychological conflict of adolescence, which is resolved positively when adolescents

achieve an identity through a process of exploration and inner soul-searching. (p. 408)

**imaginary audience** Adolescents' belief that they are the focus of everyone else's attention and concern. (p. 392)

**imitation** Learning by copying the behavior of another person. (p. 132)

**implantation** Attachment of the blastocyst to the uterine lining, which occurs 7 to 9 days after fertilization. (p. 77)

**implicit memory** Memory without conscious awareness. Distinguished from *explicit memory*. (p. 596)

**inclusive classrooms** Classrooms in which students with learning difficulties learn alongside typical students in the regular educational setting for all or part of the school day—a practice designed to prepare them for participation in society and to combat prejudices against individuals with disabilities. (p. 326)

**incomplete dominance** A pattern of inheritance in which both alleles are expressed in the phenotype, resulting in a combined trait, or one that is intermediate between the two. (p. 48)

**independence-ignorescript** A predictable pattern of interaction in which older adults' independent behaviors are mostly ignored and, as a result, occur less often. Distinguished from *dependency-support script*. (p. 616)

**independent living communities** Assisted living arrangements for older adults that provide a variety of hotel-like support services, including meals in a common dining room, housekeeping, laundry services, transportation assistance, and recreational activities. (p. 623)

**independent variable** In an experiment, the variable the investigator expects to cause changes in another variable and that the researcher manipulates by randomly assigning participants to different treatment conditions. Distinguished from *dependent variable*. (p. 33)

**induction** A type of discipline in which an adult helps make the child aware of feelings by pointing out the effects of the child's misbehavior on others. (p. 267)

**industry versus inferiority** In Erikson's theory, the psychological conflict of middle childhood, which is resolved positively when experiences lead children to develop a sense of competence at useful skills and tasks. (p. 336)

**infant-directed speech (IDS)** A form of communication used by adults to speak to infants and toddlers, consisting of short sentences with high-pitched, exaggerated expression, clear pronunciation, distinct pauses between speech segments, and repetition of new words in a variety of contexts. (p. 179)

**infantile amnesia** The inability of most older children and adults to retrieve events that happened before age 2 to 3. (p. 164)

**infant mortality** The number of deaths in the first year of life per 1,000 live births. (p. 102)

**information processing** A perspective that views the human mind as a symbol-manipulating system through which information flows and that regards cognitive development as a continuous process. (p. 19)

**inhibited, or shy, children** Children whose temperament is such that they react negatively to and withdraw from novel stimuli. Distinguished from *uninhibited, or sociable, children*. (p. 191)

**initiative versus guilt** In Erikson's theory, the psychological conflict of early childhood, which is resolved positively through play experiences that foster a healthy sense of initiative and through development of a superego, or conscience, that is not overly strict and guilt-ridden. (p. 258)

**insecure-avoidant attachment** The attachment pattern characterizing infants who seem unresponsive to the parent when she is present, are usually not distressed by parental separation, react to the stranger in much the same way as to the parent, and avoid or are slow to greet the parent when she returns. Distinguished from *secure, insecure-resistant, and disorganized/disoriented attachment*. (p. 198)

**insecure-resistant attachment** The attachment pattern characterizing infants who seek closeness to the parent and fail to explore before separation, are usually distressed when the parent leaves, and combine clinginess with angry, resistive behavior when the parent returns. Distinguished from *secure, insecure-avoidant, and disorganized/disoriented attachment*. (p. 198)

**instrumental activities of daily living (IADLs)** Tasks necessary to conduct the business of daily life and also requiring some cognitive competence, such as telephoning, shopping, food preparation, housekeeping, and paying bills. (p. 573)

**intelligence quotient (IQ)** A score that permits an individual's performance on an intelligence test to be compared to the performances of other individuals of the same age. (p. 169)

**intentional, or goal-directed, behavior** A sequence of actions in which schemes are deliberately coordinated to solve a problem. (p. 152)

**interactional synchrony** A form of communication in which the caregiver responds to infant signals in a well-timed, rhythmic, appropriate fashion and both partners match emotional states, especially the positive ones. (p. 200)

**intermodal perception** The process of making sense of simultaneous input from more than one modality, or sensory system, perceiving these separate streams of information as an integrated whole. (p. 143)

**internal working model** A set of expectations about the availability of attachment figures and their likelihood of providing support in times of stress. It becomes a vital part of personality, serving as a guide for all future close relationships. (p. 197)

**intimacy versus isolation** In Erikson's theory, the psychological conflict of early adulthood, evident in the young person's thoughts and feelings about making a long-term commitment to an intimate partner and in close, mutually gratifying friendships. (p. 476)

**irreversibility** The inability to mentally go through a series of steps in a problem and then reverse direction, returning to the starting point. Distinguished from *reversibility*. (p. 230)

## J

**joint attention** A state in which the child attends to the same object or event as the caregiver, who often labels it. Contributes to early language development. (p. 176)

## K

**kinkeeper** Role assumed by members of the middle generation, especially mothers, who take responsibility for gathering the family for celebrations and making sure everyone stays in touch. (p. 552)

**kinship studies** Studies that compare the characteristics of family members to determine the importance of heredity in complex human characteristics. (p. 67)

**kwashiorkor** A disease caused by an unbalanced diet very low in protein that usually appears after weaning, between 1 and 3 years of age. Symptoms include an enlarged belly, swollen feet, hair loss, skin rash, and irritable, listless behavior. (p. 129)

## L

**language acquisition device (LAD)** In Chomsky's theory, an innate system containing a universal grammar, or set of rules common to all languages, that enables children, no matter which language they hear, to understand and speak in a rule-oriented fashion as soon as they pick up enough words. (p. 174)

**lanugo** White, downy hair that covers the entire body of the fetus, helping the vernix stick to the skin. (p. 79)

**lateralization** Specialization of functions in the two hemispheres of the cerebral cortex. (p. 121)

**learned helplessness** Attribution of success to external factors, such as luck, and failure to low ability, which is fixed and cannot be improved by trying hard. Distinguished from *mastery-oriented attributions*. (p. 339)

**learning disabilities** Great difficulty with one or more aspects of learning, usually reading, resulting in achievement that is considerably behind what would be expected on the basis of a child's IQ. (p. 327)

**life-care communities** Assisted living arrangements for older adults that offer a continuum of housing alternatives: independent living, residences providing personal and health-related services to accommodate older adults with physical and mental disabilities, and full nursing home care. Guarantees that individuals' changing needs will be met within the same facility as they age. (p. 623)

**lifespan perspective** A developmental systems approach that assumes development is lifelong, multidimensional and multidirectional, highly plastic, and affected by multiple interacting forces. (p. 7)

**living will** A written statement specifying the treatments a person does or does not want in case of a terminal illness, coma, or other near-death situation. (p. 661)

**longitudinal design** A research design in which participants are studied repeatedly, and changes are noted as they get older. Distinguished from *cross-sectional design*. (p. 35)

**long-term memory** In information processing, the largest storage area in memory, containing our permanent knowledge base. (p. 161)

## M

**macrosystem** In ecological systems theory, the outermost level of the environment, consisting of cultural values, laws, customs, and resources that influence individuals' experiences and interactions at inner levels. Distinguished from *microsystem*, *mesosystem*, *exosystem*, and *chronosystem*. (p. 24)

**macular degeneration** Blurring and eventual loss of central vision due to a breakdown of light-sensitive cells in the macula, or central region of the retina. (p. 575)

**make-believe play** A type of play in which children act out everyday and imaginary activities. (p. 153)

**marasmus** A wasted condition of the body caused by a diet low in all essential nutrients, which usually appears in the first year of life when the mother is too malnourished to produce enough breast milk and bottle-feeding is also inadequate. (p. 129)

**mastery-oriented attributions** Attributions that credit success to ability, which can be improved through effort, and failure to factors that can be changed or controlled, such as insufficient effort or a difficult task. Distinguished from *learned helplessness*. (p. 339)

**matters of personal choice** Concerns such as choice of friends, hairstyle, and leisure activities, which do not violate rights and are up to the individual. Distinguished from *moral imperatives* and *social conventions*. (p. 272)

**maximum lifespan** The species-specific biological limit to length of life (in years), corresponding to the age at which the oldest known individual died. Distinguished from *average life expectancy* and *average healthy life expectancy*. (p. 572)

**medical aid-in-dying** At an incurably ill patient's request, a doctor's provision of a prescription for a lethal dose of drugs, which the patient self-administers to end his or her life. (p. 662)

**meiosis** The process of cell division through which gametes are formed, in which the number of chromosomes normally present in each cell is halved. (p. 45)

**memory strategies** Deliberate mental activities that improve the likelihood of remembering. (p. 240)

**menarche** First menstruation. (p. 371)

**menopause** The end of menstruation and, therefore, of a woman's reproductive capacity. (p. 510)

**mental representations** Internal depictions of information that the mind can manipulate, including images and concepts. (p. 152)

**mesosystem** In ecological systems theory, the second level of the environment, encompassing connections between an individual's microsystems, or immediate settings. Distinguished from *microsystem*, *exosystem*, *macrosystem*, and *chronosystem*. (p. 24)

**metacognition** Thinking about thought; a theory of mind, or coherent set of ideas about mental activities. (p. 241)

**methylation** A biochemical process triggered by certain experiences, in which a set of chemical compounds (called a methyl group) lands on top of a gene and changes its impact, reducing or silencing its expression. (p. 70)

**microsystem** In ecological systems theory, the innermost level of the environment, consisting of activities and interaction patterns in the person's immediate surroundings. Distinguished from *mesosystem*, *exosystem*, *macrosystem*, and *chronosystem*. (p. 23)

**midlife crisis** Self-doubt and stress that prompt major restructuring of the personality during the transition to middle adulthood. Characterizes the experience of only a minority of adults. (p. 542)

**mirror neurons** Specialized cells in motor areas of the cerebral cortex in primates that may underlie early imitative capacities by firing identically when a primate hears or sees an action and when it carries out the action on its own. (p. 132)

**moral identity** The degree to which morality is central to an individual's self-concept. (p. 418)

**moral imperatives** Rules and expectations that protect people's rights and welfare. Distinguished from *social conventions* and *matters of personal choice*. (p. 272)

**mortality** The phase of dying in which the individual passes into permanent death. Distinguished from *agonal phase* and *clinical death*. (p. 645)

**mourning** The culturally specified expression of the bereaved person's thoughts and feelings through funerals and other rituals. (p. 665)

**mutation** A sudden but permanent change in a segment of DNA. (p. 49)

**myelination** The coating of neural fibers with an insulating fatty sheath, called *myelin*, that improves the efficiency of message transfer. (p. 118)

## N

**naturalistic observation** A research method in which the investigator goes into the field, or natural environment, and records the behavior of interest. Distinguished from *structured observation*. (p. 28)

**natural, or prepared, childbirth** A group of techniques aimed at reducing pain and medical intervention and making childbirth a rewarding experience. (p. 95)

**nature–nurture controversy** Disagreement among theorists about whether genetic or environmental factors are more important influences on development. (p. 7)

**neglected children** Children who are seldom mentioned, either positively or negatively, on self-report measures of peer acceptance. Distinguished from *popular*, *rejected*, and *controversial children*. (p. 347)

**Neonatal Behavioral Assessment Scale (NBAS)** A test used to evaluate a newborn's reflexes, muscle tone, state changes, responsiveness to physical and social stimuli, and other reactions. (p. 110)

**neural tube** During the period of the embryo, the primitive spinal cord that develops from the ectoderm, the top of which swells to form the brain. (p. 78)

**neurofibrillary tangles** A structural change in the cerebral cortex associated with Alzheimer's disease, in which bundles of twisted threads appear that are the product of collapsed neural structures and that contain abnormal forms of a protein called tau. (p. 588)

**neurons** Nerve cells that store and transmit information. (p. 117)

**neurotransmitters** Chemicals released by neurons that cross the synapse to send messages to other neurons. (p. 117)

**niche-picking** A type of gene–environment correlation in which individuals actively choose environments that complement their heredity. (p. 69)

**nonnormative influences** Influences on lifespan development that are irregular, in that they happen to just one person or a few people and do not follow a predictable timetable. (p. 10)

**non-rapid-eye-movement (NREM) sleep** A “regular” sleep state during which the body is almost motionless and heart rate, breathing, and brain-wave activity are slow and even. Distinguished from *rapid-eye-movement (REM) sleep*. (p. 104)

**nonsocial activity** Unoccupied, onlooker behavior and solitary play. Distinguished from *parallel*, *associative*, and *cooperative play*. (p. 263)

**normal distribution** The bell-shaped distribution that results when researchers measure individual differences in large samples. Most scores cluster around the mean, or average, with progressively fewer falling toward the extremes. (p. 169)

**normative approach** An approach in which measures of behavior are taken on large numbers of individuals, and age-related averages are computed to represent typical development. (p. 14)

## O

**obesity** A greater-than-20-percent increase over healthy weight, based on body mass index (BMI), a ratio of weight to height associated with body fat. (p. 295)

**object permanence** The understanding that objects continue to exist when out of sight. (p. 152)

**operant conditioning** A form of learning in which a spontaneous behavior is followed by a stimulus that changes the probability that the behavior will occur again. (p. 131)

**ordinality** The mathematical principle specifying order relationships (more than and less than) between quantities. (p. 244)

**organization** In Piaget's theory, the internal rearrangement and linking of schemes to create a strongly interconnected cognitive system. In information processing, a memory strategy that involves grouping related items together to improve recall. (p. 150, p. 310)

**osteoarthritis** A form of arthritis that involves deteriorating cartilage on the ends of bones of frequently used joints, leading to swelling, stiff-

ness, and loss of flexibility. Also known as “wear-and-tear” arthritis or “degenerative joint disease.” Distinguished from *rheumatoid arthritis*. (p. 585)

**osteoporosis** Severe age-related bone loss, which greatly magnifies the risk of bone fractures. (p. 519)

**overextension** An early vocabulary error in which young children apply a word too broadly, to a wider collection of objects and events than is appropriate. Distinguished from *underextension*. (p. 177)

**overregularization** Overextension of regular grammatical rules to words that are exceptions. (p. 251)

## P

**palliative, or comfort, care** Care for terminally ill, suffering patients that relieves pain and other symptoms (nausea, breathing difficulties, insomnia, and depression), with the goal of protecting the patient's quality of remaining life rather than prolonging life. (p. 658)

**parallel play** A form of limited social participation in which a child plays near other children with similar materials but does not try to influence their behavior. Distinguished from *nonsocial activity*, *associative play*, and *cooperative play*. (p. 263)

**partial fetal alcohol syndrome (p-FAS)** A form of fetal alcohol spectrum disorder characterized by facial abnormalities and brain injury, but less severe than fetal alcohol syndrome. Usually affects children whose mothers drank alcohol in smaller quantities during pregnancy. Distinguished from *fetal alcohol syndrome (FAS)* and *alcohol-related neurodevelopmental disorder (ARND)*. (p. 84)

**passionate love** Love based on intense sexual attraction. Distinguished from *companionate love* and *compassionate love*. (p. 479)

**peer acceptance** Likability, or the extent to which a child is viewed by a group of agemates as a worthy social partner. (p. 347)

**peer groups** Collectives of peers who generate unique values and standards for behavior and a social structure of leaders and followers. (p. 346)

**peer victimization** A destructive form of peer interaction in which certain children become frequent targets of verbal and physical attacks or other forms of abuse. (p. 349)

**perceptual narrowing effect** Perceptual sensitivity that becomes increasingly attuned with age to information most often encountered. (p. 139)

**permissive child-rearing style** A child-rearing style that is warm and accepting but uninvolved, low in control (either overindulgent or inattentive), and lenient rather than appropriate in autonomy granting. Distinguished from *authoritative*, *authoritarian*, and *uninvolved child-rearing styles*. (p. 283)

**persistent vegetative state** A state in which the cerebral cortex no longer registers electrical activity but the brain stem remains active. The person is unconscious and displays no voluntary movements. (p. 647)

**personal fable** Adolescents' inflated opinion of their own importance—a feeling that they are special and unique. (p. 386)

**person–environment fit** A good match between older adults' abilities and the demands of their living environments, which promotes adaptive behavior and psychological well-being. (p. 616)

**person praise** Praise that emphasizes a child's traits, such as “You're so smart!” Distinguished from *process praise*. (p. 339)

**phenotype** An individual's directly observable physical and behavioral characteristics, which are determined by both genetic and environmental factors. Distinguished from *genotype*. (p. 43)

**phobia** An intense, unmanageable fear that leads to persistent avoidance of the feared situation. (p. 358)

**phonics approach** An approach to beginning reading instruction that emphasizes coaching children on *phonics*—the basic rules for translating written symbols into sounds—before exposing them to complex reading material. Distinguished from *whole-language approach*. (p. 313)

**phonological awareness** The ability to reflect on and manipulate the sound structure of spoken language, as indicated by sensitivity to changes in sounds within words, to rhyming, and to incorrect pronunciation. A strong predictor of emergent literacy knowledge. (p. 244)

**physical aggression** A form of aggression that harms others through physical injury to themselves or their property. Distinguished from *verbal aggression* and *relational aggression*. (p. 272)

**pituitary gland** A gland located at the base of the brain that releases hormones that induce physical growth. (p. 219)

- placenta** The organ that permits food and oxygen to reach the developing organism and waste products to be carried away, while also preventing the mother's and embryo's blood from mixing directly. (p. 78)
- plasticity** Openness of development to change in response to influential experiences. (p. 7)
- polygenic inheritance** A pattern of inheritance in which many genes influence a characteristic. (p. 50)
- popular-antisocial children** A subgroup of popular children who are admired for their socially adept yet belligerent behavior. Includes "tough" boys—athletically skilled but poor students who cause trouble and defy authority—and relationally aggressive boys and girls who enhance their own status by ignoring, excluding, and spreading rumors about other children. Distinguished from *popular-prosocial children*. (p. 348)
- popular children** Children who receive many positive votes on self-report measures of peer acceptance, indicating they are well-liked. Distinguished from *rejected*, *controversial*, and *neglected children*. (p. 347)
- popular-prosocial children** A subgroup of popular children who combine academic and social competence and are both well-liked and admired. Distinguished from *popular-antisocial children*. (p. 348)
- positivity effect** An emotional strength of older adults who, compared with younger people, selectively attend to and better recall emotionally positive over negative information. (p. 611)
- possible selves** The temporal dimension of self-concept—future-oriented representations of what one is striving for and what one is attempting to avoid. (p. 544)
- postconventional level** Kohlberg's highest level of moral development, in which individuals define morality in terms of abstract principles and values that apply to all situations and societies. (p. 415)
- postformal thought** Cognitive development beyond Piaget's formal operational stage. (p. 456)
- practical problem solving** Problem solving that requires people to size up real-world situations and analyze how best to achieve goals that have a high degree of uncertainty. (p. 530)
- pragmatics** The practical, social side of language, concerned with how to engage in effective and appropriate communication. (p. 252)
- pragmatic thought** In Labouvie-Vief's theory, a structural advance in thinking in adulthood, in which logic becomes a tool for solving real-world problems and contradictions are accepted as part of existence. (p. 458)
- preconventional level** Kohlberg's first level of moral development, in which children accept the rules of authority figures and judge actions by their consequences, viewing behaviors that result in punishment as bad and those that lead to rewards as good. (p. 414)
- prefrontal cortex** The region of the cerebral cortex, lying in front of areas controlling body movement, that is responsible for thought—in particular, consciousness, inhibition of impulses, integration of information, and memory, reasoning, planning, and problem-solving strategies. (p. 120)
- prenatal diagnostic methods** Medical procedures that permit detection of developmental problems before birth. (p. 53)
- preoperational stage** Piaget's second stage of cognitive development, extending from about 2 to 7 years of age, in which children undergo an extraordinary increase in representational, or symbolic, activity, although thought is not yet logical. (p. 227)
- presbycusis** Age-related hearing impairment, beginning around age 50 with a noticeable decline in sensitivity to high-frequency sounds, which gradually extends to all frequencies. (p. 509)
- presbyopia** A condition of aging in which, around age 60, the lens of the eye loses its capacity to adjust to objects at varying distances. (p. 508)
- preterm infants** Infants born several weeks or more before their due date. (p. 98)
- primary aging** Genetically influenced age-related declines in the functioning of organs and systems that affect all members of our species and occur even in the context of overall good health. Also called *biological aging*. Distinguished from *secondary aging*. (p. 585)
- primary sexual characteristics** Physical features that involve the reproductive organs (ovaries, uterus, and vagina in females; penis, scrotum, and testes in males). Distinguished from *secondary sexual characteristics*. (p. 371)
- private speech** Self-directed speech that children use to plan and guide their own behavior. (p. 234)
- proactive aggression** A type of aggression in which children act to fulfill a need or desire—to obtain an object, privilege, space, or social reward, such as adult or peer attention—and unemotionally attack a person to achieve their goal. Also called *instrumental aggression*. Distinguished from *reactive aggression*. (p. 272)
- problem-centered coping** A strategy for managing emotion that involves appraising the situation as changeable, identifying the difficulty, and deciding what to do about it. Distinguished from *emotion-centered coping*. (p. 342)
- process praise** Praise that emphasizes behavior and effort, such as "You figured it out!" Distinguished from *person praise*. (p. 339)
- programmed cell death** An aspect of brain growth in which, as synapses form, many surrounding neurons die, making space for these connective structures. (p. 118)
- Project Head Start** The most extensive U.S. federally funded preschool program, which provides low-SES children with a year or two of preschool education, along with nutritional and health services, and encourages parent involvement in children's learning and development. (p. 246)
- propositional thought** A type of formal operational reasoning involving the ability to evaluate the logic of propositions, or verbal statements, without referring to real-world circumstances. (p. 389)
- prosocial, or altruistic, behavior** Actions that benefit another person without any expected reward for the self. (p. 262)
- prospective memory** Recall that involves remembering to engage in planned actions in the future. (p. 598)
- protein-coding genes** Genes that directly affect our body's characteristics by sending instructions for making a rich assortment of proteins to the cytoplasm surrounding the cell nucleus. (p. 44)
- proximodistal trend** An organized pattern of physical growth that proceeds from the center of the body outward ("near to far"). Distinguished from *cephalocaudal trend*. (p. 117)
- psychoanalytic perspective** An approach to personality development introduced by Freud that assumes people move through a series of stages in which they confront conflicts between biological drives and social expectations. How these conflicts are resolved determines the person's ability to learn, to get along with others, and to cope with anxiety. (p. 14)
- psychological control** Parental behaviors that intrude on and manipulate children's verbal expressions, individuality, and attachments to parents. (p. 283)
- psychosexual theory** Freud's theory, which emphasizes that how parents manage children's sexual and aggressive drives in the first few years is crucial for healthy personality development. (p. 14)
- psychosocial theory** Erikson's theory, which emphasizes that in each Freudian stage, individuals not only develop a unique personality but also acquire attitudes and skills that make them active, contributing members of their society. Recognizes the lifespan nature of development. (p. 15)
- puberty** Biological changes at adolescence that lead to an adult-sized body and sexual maturity. (p. 367)
- public policies** Laws and government programs designed to improve current conditions. (p. 64)
- punishment** In operant conditioning, removal of a desirable stimulus or presentation of an unpleasant one to decrease the occurrence of a response. (p. 131)
- R**
- random assignment** An unbiased procedure for assigning participants to treatment conditions in an experiment, such as drawing numbers out of a hat or flipping a coin. Increases the chances that participants' characteristics will be equally distributed across treatment groups. (p. 33)
- rapid-eye-movement (REM) sleep** An irregular sleep state in which brain-wave activity is similar to that of the waking state. Distinguished from *non-rapid-eye-movement (NREM) sleep*. (p. 104)
- reactive aggression** An angry, defensive response to provocation or a blocked goal, which is meant to hurt another person. Also called *hostile aggression*. Distinguished from *proactive aggression*. (p. 272)
- realistic period** Period of vocational development in which older adolescents and young adults narrow their vocational options, engaging in

- further exploration before focusing on a general vocational category and, slightly later, settling on a single occupation. Distinguished from *fantasy period* and *tentative period*. (p. 462)
- recall** A type of memory that involves remembering something that is not present. Distinguished from *recognition*. (p. 163)
- recasts** Adult responses that restructure children's grammatically inaccurate speech into correct form. (p. 252)
- recognition** A type of memory that involves noticing when a stimulus is identical or similar to one previously experienced. Distinguished from *recall*. (p. 163)
- recovery** Following habituation, an increase in responsiveness to a new stimulus. (p. 131)
- recursive thought** A form of perspective taking that involves the ability to view a situation from at least two perspectives—that is, to reason simultaneously about what two or more people are thinking. (p. 312)
- referential style of language learning** A style of early language learning in which toddlers use language mainly to name things, producing many words that refer to objects. Distinguished from *expressive style of language learning*. (p. 178)
- reflex** An inborn, automatic response to a particular form of stimulation. (p. 101)
- regulator genes** Genes that modify the instructions given by protein-coding genes, greatly complicating their genetic impact. (p. 44)
- rehearsal** A memory strategy that involves repeating information to oneself. (p. 310)
- reinforcer** In operant conditioning, a stimulus that increases the occurrence of a response. (p. 131)
- rejected-aggressive children** A subgroup of rejected children who show high rates of conflict, physical and relational aggression, and hyperactive, inattentive, and impulsive behavior. Distinguished from *rejected-withdrawn children*. (p. 348)
- rejected children** Children who receive many negative votes on self-report measures of peer acceptance, indicating they are actively disliked. Distinguished from *popular, controversial, and neglected children*. (p. 347)
- rejected-withdrawn children** A subgroup of rejected children who are passive and socially awkward. Distinguished from *rejected-aggressive children*. (p. 348)
- relational aggression** A form of aggression that damages another's peer relationships through social exclusion, malicious gossip, or friendship manipulation. Distinguished from *physical aggression* and *verbal aggression*. (p. 272)
- relativistic thinking** In Perry's theory, the cognitive approach typical of older college students, who view all knowledge as embedded in a framework of thought and, therefore, give up the possibility of absolute truth in favor of multiple truths, each relative to its context. Distinguished from *dualistic thinking*. (p. 457)
- remembrance** The process of telling stories about people and events from the past and reporting associated thoughts and feelings. (p. 612)
- remembrance bump** Older adults' heightened autobiographical memory for events that occurred between ages 10 and 30. (p. 597)
- remote memory** Very long-term episodic recall. (p. 597)
- resilience** The ability to adapt effectively in the face of threats to development. (p. 10)
- reticular formation** A structure in the brain stem that maintains alertness and consciousness. (p. 218)
- reversibility** The capacity to think through a series of steps in a problem and then mentally reverse direction, returning to the starting point. Distinguished from *irreversibility*. (p. 304)
- rheumatoid arthritis** A form of arthritis in which an autoimmune response leads to inflammation of connective tissue, particularly the membranes that line the joints, resulting in overall aching, inflammation, and stiffness. Leads to deformed joints and often serious loss of mobility. Distinguished from *osteoarthritis*. (p. 585)
- Rh factor incompatibility** A condition that arises when the Rh protein is present in the fetus's blood but not in the mother's, causing the mother to build up antibodies. If these enter the fetus's system, they destroy red blood cells, reducing the oxygen supply to organs and tissues. Intellectual disability, miscarriage, heart damage, and infant death can occur. (p. 89)
- rough-and-tumble play** A form of peer interaction involving friendly chasing and play-fighting that emerges in the preschool years and peaks in middle childhood. In our evolutionary past, it may have been important for developing fighting skill. (p. 302)
- S**
- sandwich generation** A term used to describe middle-aged adults who must care for multiple generations above and below them at the same time. (p. 555)
- scaffolding** Adjusting the support offered during a teaching session to fit the learner's current level of performance. As competence increases, effective scaffolders gradually and sensitively withdraw support, turning over responsibility to the learner. (p. 235)
- scale errors** Toddlers' attempts to do things that their body size makes impossible, such as trying to put on dolls' clothes, sit in a doll-sized chair, or walk through a door too narrow to pass through. (p. 207)
- schemes** In Piaget's theory, specific psychological structures, or organized ways of making sense of experience, that change with age. (p. 150)
- scripts** General descriptions of what occurs and when it occurs in a particular situation, used to organize and interpret routine experiences. (p. 240)
- secondary aging** Age-related declines due to hereditary defects and environmental influences, such as poor diet, lack of exercise, disease, substance abuse, environmental pollution, and psychological stress. Distinguished from *primary aging*. (p. 585)
- secondary friends** People who are not intimates but with whom an individual spends time occasionally, such as a group that meets for lunch, bridge, or museum tours. (p. 631)
- secondary sexual characteristics** Physical features visible on the outside of the body that serve as signs of sexual maturity but do not involve the reproductive organs (for example, breast development in females, appearance of underarm and pubic hair in both sexes). Distinguished from *primary sexual characteristics*. (p. 371)
- secular trend** A change from one generation to the next in an aspect of development, such as body size or pubertal timing. (p. 373)
- secure attachment** The attachment pattern characterizing infants who use the parent as a secure base from which to explore, may be distressed by separation from the parent, but convey clear pleasure and are easily comforted when the parent returns. Distinguished from *insecure-avoidant, insecure-resistant, and disorganized/disoriented attachment*. (p. 198)
- secure base** The familiar caregiver as a point from which the baby explores, venturing into the environment and then returning for emotional support. (p. 186)
- selective optimization with compensation** A set of strategies used by older adults who sustain high levels of functioning. Narrowing their goals, they *select* personally valued activities to *optimize* (or maximize) returns from their diminishing energy and also find new ways to *compensate* for losses. (p. 595)
- self-care children** Children who are without adult supervision for some period of time after school. (p. 351)
- self-concept** The set of attributes, abilities, attitudes, and values that an individual believes defines who he or she is. (p. 258)
- self-conscious emotions** Emotions involving injury to or enhancement of the sense of self, including guilt, shame, embarrassment, envy, and pride. (p. 188)
- self-esteem** An aspect of self-concept that involves judgments about one's own worth and the feelings associated with those judgments. (p. 260)
- self-recognition** Identification of the self as a physically unique being. (p. 207)
- semantic memory** Memory for information removed from the context in which it was first learned that has become part of an individual's general knowledge base. Distinguished from *episodic memory*. (p. 240)
- sensitive caregiving** Caregiving that involves responding promptly, consistently, and appropriately to infants and holding them tenderly and carefully. (p. 200)
- sensitive period** A time that is biologically optimal for certain capacities to emerge because the individual is especially responsive to environmental influences. Development can occur later, but it is harder to induce. (p. 21)
- sensorimotor stage** Piaget's first stage, spanning the first two years of life, during which infants and toddlers "think" with their eyes, ears, hands, and other sensorimotor equipment. (p. 152)
- sensory register** The part of the information-processing system in which sights and sounds are represented directly and stored briefly. (p. 160)

- separation anxiety** An infant's distressed reaction to the departure of the familiar caregiver. (p. 197)
- seriation** The ability to order items along a quantitative dimension, such as length or weight. (p. 304)
- sequential designs** Developmental designs in which investigators conduct several similar cross-sectional or longitudinal studies (called *sequences*) at varying times, sometimes combining longitudinal and cross-sectional strategies. (p. 36)
- sex chromosomes** The twenty-third pair of chromosomes, which determines the sex of the individual. In females, it is called *XX*; in males, *XY*. (p. 45)
- short-term memory store** The part of the mind in which attended-to information is retained briefly so we can actively "work on" it to reach our goals. (p. 160)
- skipped-generation family** A family structure in which children live with grandparents but apart from parents. (p. 554)
- sleep apnea** A condition in which breathing ceases for 10 seconds or longer during sleep, resulting in many brief awakenings. (p. 577)
- slow-to-warm-up child** A child whose temperament is characterized by inactivity; mild, low-key reactions to environmental stimuli; negative mood; and slow adjustment to new experiences. Distinguished from *easy child* and *difficult child*. (p. 190)
- small-for-date infants** Infants whose birth weight is below their expected weight considering length of the pregnancy. Some are full-term; others are preterm infants who are especially underweight. (p. 98)
- social clock** Age-graded expectations for major life events, such as beginning a first job, getting married, birth of the first child, buying a home, and retiring. (p. 478)
- social comparisons** Judgments of one's own appearance, abilities, and behavior in relation to those of others. (p. 336)
- social-constructivist classroom** A classroom grounded in Vygotsky's sociocultural theory, in which children participate in a wide range of challenging activities with teachers and peers, with whom they jointly construct understandings. Distinguished from *traditional* and *constructivist classrooms*. (p. 325)
- social conventions** Customs determined solely by consensus within a society, such as table manners and politeness rituals. Distinguished from *moral imperatives* and *matters of personal choice*. (p. 272)
- social convoy** A model of age-related changes in social networks, which views the individual as moving through life within a cluster of relationships, with close ties in the inner circle and less close ties on the outside. With age, people change places in the convoy, new ties are added, and some drift off. (p. 625)
- social learning theory** An approach that emphasizes the role of *modeling*, also known as *imitation* or *observational learning*, as a powerful source of development. (p. 17)
- social referencing** Actively seeking emotional information from a trusted person in an uncertain situation. (p. 188)
- social smile** The infant's broad grin, evoked by the parent's communication, that first appears between 6 and 10 weeks of age. (p. 185)
- sociocultural theory** Vygotsky's theory, in which children acquire the ways of thinking and behaving that make up their community's culture through *social interaction*—in particular, cooperative dialogues with more knowledgeable members of society. (p. 22)
- sociodramatic play** The make-believe with others that is under way by the end of the second year and increases rapidly in complexity during early childhood. (p. 228)
- socioeconomic status (SES)** A measure of an individual's or a family's social position and economic well-being that combines three related, but not completely overlapping, variables: years of education, the prestige of one's job and the skill it requires, and income. (p. 58)
- socioemotional selectivity theory** A social theory of aging that states that social interaction in late adulthood extends lifelong selection processes. Aging leads to an increased emphasis on the emotion-regulating function of social interaction, causing older adults to prefer familiar social partners with whom they have developed pleasurable relationships. (p. 620)
- spermarche** First ejaculation of seminal fluid. (p. 372)
- stages** Qualitative changes in thinking, feeling, and behaving that characterize specific periods of development. (p. 6)
- standardization** The practice of giving a newly constructed test to a large, representative sample and using the results as the standard for interpreting individual scores. (p. 169)
- states of arousal** Different degrees of sleep and wakefulness. (p. 108)
- statistical learning capacity** Infants' capacity to analyze the speech stream for patterns—repeatedly occurring sequences of sounds—through which they acquire a stock of speech structures for which they will later learn meanings. (p. 138)
- stereotype threat** The fear of being judged on the basis of a negative stereotype, which can trigger anxiety that interferes with performance. (p. 320)
- stranger anxiety** The infant's expression of fear in response to unfamiliar adults, which appears in many babies in the second half of the first year. (p. 186)
- Strange Situation** A laboratory procedure used to assess the quality of attachment between 1 and 2 years of age by observing the baby's response to eight short episodes involving brief separations from and reunions with the caregiver in an unfamiliar playroom. (p. 197)
- structured interview** An interview method in which the researcher asks each participant the same set of questions in the same way. Distinguished from *clinical interview*. (p. 30)
- structured observation** A research method in which the investigator sets up a laboratory situation that evokes the behavior of interest so that every participant has equal opportunity to display the response. Distinguished from *naturalistic observation*. (p. 28)
- subcultures** Groups of people with beliefs and customs that differ from those of the larger culture. (p. 62)
- successful aging** Aging in which gains are maximized and losses minimized, enabling realization of individual potential. (p. 637)
- sudden infant death syndrome (SIDS)** The unexpected death, usually during the night, of an infant younger than 1 year of age that remains unexplained after thorough investigation. (p. 106)
- sympathy** Feelings of concern or sorrow for another's plight. (p. 263)
- synapses** The gaps between neurons, across which chemical messages are sent. (p. 117)
- synaptic pruning** A process in which neurons that are seldom stimulated lose their synapses and are returned to an uncommitted state so they can support future development. (p. 118)
- T**
- talent** Outstanding performance in a specific field. (p. 328)
- telegraphic speech** Toddlers' two-word utterances that, like a telegram, focus on high-content words while omitting smaller, less important words. (p. 177)
- telomeres** A special type of DNA located at the ends of chromosomes—serving as a "cap" to protect the ends from destruction—that shortens with each cell duplication. Eventually, so little remains that the cells no longer duplicate at all. (p. 438)
- temperament** Early-appearing, stable individual differences in reactivity (quickness and intensity of emotional arousal, attention, and motor activity) and self-regulation (strategies that modify that reactivity). (p. 190)
- tentative period** Period of vocational development in which adolescents begin to evaluate vocational options in terms of their interests, abilities, and values. Distinguished from *fantasy period* and *realistic period*. (p. 462)
- teratogen** Any environmental agent that causes damage during the prenatal period. (p. 81)
- terminal decline** Acceleration in deterioration of cognitive functioning prior to death. (p. 601)
- thanatology** An interdisciplinary field devoted to the study of death and dying. (p. 645)
- theory** An orderly, integrated set of statements that describes, explains, and predicts behavior. (p. 5)
- theory of multiple intelligences** Gardner's theory, which identifies at least eight independent intelligences—linguistic, logico-mathematical, musical, spatial, bodily-kinesthetic, naturalist, interpersonal, and intrapersonal—defined in terms of distinct sets of processing operations that permit individuals to engage in a wide range of culturally valued activities. (p. 316)
- Third Age** A new phase of late adulthood extending from ages 65 to 79 or longer, resulting from added years of longevity and health plus financial

stability, in which older adults pursue personally enriching interests and goals. (p. 613)

**thyroid-stimulating hormone (TSH)** A pituitary hormone that prompts the thyroid gland to release *thyroxine*, which is necessary for brain development and for growth hormone to have its full impact on body size. (p. 219)

**time out** A form of mild punishment that involves removing children from the immediate setting until they are ready to act appropriately. (p. 269)

**traditional classroom** A classroom in which the teacher is the sole authority for knowledge, rules, and decision making and students are relatively passive learners whose progress is evaluated by how well they keep pace with a uniform set of standards for their grade. Distinguished from *constructivist* and *social-constructivist classrooms*. (p. 324)

**traditional marriage** A form of marriage involving clear division of roles—husband as head of household responsible for family economic well-being, wife as caregiver and homemaker. Distinguished from *egalitarian marriage*. (p. 486)

**transitive inference** The ability to seriate, or order items along a quantitative dimension, mentally. (p. 304)

**triangular theory of love** Sternberg's view of love as including three components—*passion*, *intimacy*, and *commitment*—that shift in emphasis as romantic relationships develop. (p. 479)

**triarchic theory of successful intelligence** Sternberg's theory, in which intelligent behavior involves balancing three broad, interacting intelligences—analytical, creative, and practical—to achieve success in life according to one's personal goals and the requirements of one's cultural community. (p. 316)

**trimesters** Three equal time periods, each lasting three months, into which prenatal development is sometimes divided. (p. 79)

**Type A behavior pattern** A behavior pattern characterized by extreme competitiveness, ambition, impatience, hostility, angry outbursts, and a sense of eagerness, hurriedness, and time pressure. (p. 519)

## U

**umbilical cord** The long cord connecting the developing organism to the placenta that delivers nutrients and removes waste products. (p. 78)

**unconditioned response (UCR)** In classical conditioning, a reflexive response that is consistently produced by an unconditioned stimulus (UCS). Distinguished from *conditioned response*. (p. 130)

**unconditioned stimulus (UCS)** In classical conditioning, a stimulus that consistently produces a reflexive response. Distinguished from *conditioned stimulus*. (p. 130)

**underextension** An early vocabulary error in which young children apply a word too narrowly, to a smaller number of objects and events than is appropriate. Distinguished from *overextension*. (p. 177)

**uninhibited**, or sociable, children Children whose temperament is such that they display positive emotion to and approach novel stimuli. Distinguished from *inhibited*, or *shy*, children. (p. 191)

**uninvolved child-rearing style** A child-rearing style that combines low acceptance and involvement with little control and general indifference to issues of autonomy. Distinguished from *authoritative*, *authoritarian*, and *permissive child-rearing styles*. (p. 283)

## V

**vascular dementia** A form of dementia that develops when a series of strokes leaves areas of dead brain cells, producing step-by-step degeneration of mental ability, with each step occurring abruptly after a stroke. (p. 590)

**verbal aggression** A type of aggression that harms others through threats of physical aggression, name-calling, or hostile teasing. Distinguished from *physical aggression* and *relational aggression*. (p. 272)

**vernix** A white, cheeselike substance that covers the fetus, preventing the skin from chapping due to constant exposure to amniotic fluid. (p. 79)

**video deficit effect** In toddlers, poorer performance on tasks after watching a video than after seeing a live demonstration. (p. 157)

**violation-of-expectation method** A method in which researchers show babies an expected event (one that is consistent with reality) and an unexpected event (a variation of the first event that violates reality). Heightened attention to the unexpected event suggests that the infant is "surprised" by a deviation from physical reality and, therefore, is aware of that aspect of the physical world. (p. 153)

**visual acuity** Fineness of visual discrimination. (p. 109)

**voluntary euthanasia** At a patient's request, the practice of actively taking the patient's life in a painless way for the purpose of relieving suffering. (p. 664)

## W

**whole-language approach** An approach to beginning reading instruction in which children are exposed to text in its complete form, using reading materials that are whole and meaningful, to promote appreciation of the communicative function of written language. Distinguished from *phonics approach*. (p. 313)

**wisdom** A capacity made up of multiple cognitive and personality traits, combining breadth and depth of practical knowledge; ability to reflect on and apply that knowledge in ways that make life more bearable and worthwhile; emotional maturity, including the ability to listen patiently and empathetically and give sound advice; and an altruistic form of creativity that involves contributing to humanity and enriching others' lives. (p. 600)

**working memory** The number of items that can be briefly held in mind while also engaging in some effort to monitor or manipulate those items—a "mental workspace" that we use to accomplish many activities in daily life. A contemporary view of the short-term memory store. (p. 161)

## X

**X-linked inheritance** A pattern of inheritance in which a harmful allele is carried on the X chromosome, so that males are more likely than females to be affected. (p. 48)

## Z

**zone of proximal development** In Vygotsky's theory, a range of tasks too difficult for a child to handle alone but possible with the help of more skilled partners. (p. 166)

**zygote** The newly fertilized cell formed by the union of sperm and ovum at conception. (p. 45)
